CHAPTER 1

Introduction

INTRODUCTION TO THIS MANUAL

This is the common language reference manual for the Absoft Fortran 77, Fortran 90, and Fortran 95 implementations. Operating systems supported on the platforms include: Windows, Linux, and Macintosh OS X. Absoft Fortran compilers in these environments are 100% source compatible and most control options are identical. Options relevant only to a specific environment are noted as such.

INTRODUCTION TO ABSOFT FORTRAN

Absoft Fortran is a complete implementation of the FORTRAN programming languages: FORTRAN 77, Fortran 90, and Fortran 95. It also completely implements ISO Technical Reports TR15580 and TR15581. The microprocessor-based computers of today are vastly more powerful and sophisticated than their predecessors. They offer more RAM, faster clock speeds, advanced scheduling and multiple core capabilities at very low prices..

Absoft Fortran is designed especially for these modern CPUs. It is not an evolutionary descendent of older compiler technology. Absoft Fortran brings a complete software development tool set with exceptional flexibility and improved ease-of-use to modern personal computers.

COMPATIBILITY

Absoft Fortran provides excellent compatibility with code developed on mainframes and workstations. Most popular VAX/VMS statement extensions are accepted, as well as several from IBM/VS, Cray, Sun, and others. See the chapter **Porting Code** in the *Pro Fortran User Guide* for additional compatibility information.

CONVENTIONS USED IN THIS MANUAL

There are a few typographic and syntactic conventions used throughout this manual for clarity.

- [] square brackets indicate that a syntactic item is optional.
- ... indicates a repetition of a syntactic element.
- Term definitions are underlined.
- **-option** font indicates a compiler option.
- *Italics* is used for emphasis and book titles.
- On-screen text such as menu titles and button names look the same as in pictures and on the screen (e.g. the **File** menu).
- The modifier keys on PC keyboards are Shift, Alt, and Control. They are always used with other keys and are referenced as in the following:

Shift-G	press the Shift and 'G' keys together
Alt-F4	press the Alt and F4 function keys together
Control-C	press the Control and 'C' keys together

- Unless otherwise indicated, all numbers are in decimal form.
- FORTRAN examples appear in the following form:

```
PROGRAM SAMPLE
WRITE(9,*) "Hello World!"
END
```

- Absoft extensions are highlighted in gray in this manual.

CHAPTER 2

The Fortran Program

Fortran source programs consist of one program unit called the main program and any number of related program units called subprograms. A program or program unit is constructed as an ordered set of statements that describes procedures for execution and information to be used by the Fortran compiler during the compilation of a source program. Every program unit is written using the Fortran character set and follows a prescribed statement line format. A program unit may be one of the following:

- Main program
- Subroutine subprogram
- Function subprogram
- External subprogram
- Module
- Block Data subprogram

This chapter describes the format of Fortran programs and the data objects that may be manipulated by them.

CHARACTER SET

The compiler's character set consists of the following characters:

- Uppercase and lowercase letters: A–Z, a–z
- Digits: 0–9
- Blank character
- Special characters: + – * / = . , () \$ ' _ : % ! < > " &

Any of these characters, as well as the remaining printable ASCII characters, may appear in character and Hollerith constants (see below).

SYMBOLIC NAMES

A symbolic name is used to identify a Fortran entity, such as a variable, array, program unit, module, or labeled common block. The first character of a symbolic name must be a letter. Additional characters may be letters, digits, or the underscore (`_`) character. A symbolic name may contain up to 31 significant characters. Symbolic names of greater than 31 characters are acceptable, but only the first 31 characters are significant to the compiler.

The blank character may not be used within a Fortran 95 source format symbolic name. The blank character is not significant in a Fortran 77 source format symbolic name but may be used as a separator.

Global symbolic names are known to every program unit within an executable program and therefore must be unique. The names of main programs; subroutine, function, block data subprograms; modules; and common blocks are examples of global symbolic names.

Local symbolic names are known only within the program unit in which they occur. The names of variables, arrays, symbolic constants, statement functions, contained subprograms, and dummy procedures are local symbolic names.

KEYWORDS

A keyword is a sequence of characters that has a predefined meaning to the compiler. A keyword is used to identify a statement or serve as a separator in a statement. Some typical statement identifiers are `READ`, `FORMAT`, and `REAL`. Two separators are `TO` and `THEN`.

There are no reserved words in Fortran, therefore a symbolic name may assume the exact sequence of characters as a keyword. The compiler determines the meaning of a sequence of characters through the context in which the characters are used. A surprising example of a keyword/symbolic name exchange is:

<u>Statement</u>	<u>Meaning</u>
<code>DO10I=1,7</code>	Control statement
<code>DO 10 I = 1. 7</code>	Assignment statement

Note that the embedded blanks are not significant in Fortran 77 source format nor are they required as separators for the compiler to determine that the first statement is the initial statement of a `DO` loop. The absence of a comma in the second statement informs the compiler that an assignment is to be made to the variable whose symbolic name is `DO10I`.

In Fortran 95 source format, blanks are required as separators.

LABELS

A statement label may appear on a Fortran statement initial line. Actual placement of a label on the initial line is governed by rules described later in this chapter in the section **Statement Format**. A statement label is used for reference in other statements. The following considerations govern the use of the statement label:

- The label is an unsigned integer in the range of 1 to 99999.
- Leading zeros not significant to the compiler.
- A label must be unique within a program unit.
- A label is not allowed on a continuation line.
- Labels may appear in any numeric order.

Examples of labels:

```
1101
88
10
010
```

The last two examples produce the same label.

STATEMENTS

Individual statements deal with specific aspects of a procedure described in a program unit and are classified as either executable or nonexecutable. The proper usage and construction of the various types of statements is described in the following chapters.

Executable Statements

Executable statements specify actions and cause the Fortran compiler to generate executable program instructions. There are 3 types of executable statements:

- Assignment statements
- Control statements
- Input/Output statements

Nonexecutable Statements

Nonexecutable statements are used as directives to the compiler: start a new program unit, allocate variable storage, initialize data, set the options, etc. There are 9 types of nonexecutable statements:

- Specification statements
- Data initialization statements
- `FORMAT` statements
- Function defining statements
- Subprogram statements
- Main program statements
- Module statements
- Interface statements
- Compiler directives

Statement Format

A FORTRAN statement consists of one or more source records referred to as a statement line. Historically, a record is equivalent to a card. In current source file formats, a record is one line of text terminated by an end of record character (generally a line feed, or carriage return-line feed pair).

Two statement formats are supported by the compiler and are described in the following sections.

FORTRAN 77 fixed format is selected if the file name ends with `.f`, `.for`, or the compiler options **-f fixed** is specified.

Fortran 90 free format is selected if the file name ends with `.f90`, `.f95`, or the compiler options **-f free** is specified.

FORTRAN 77 Fixed Format

A FORTRAN 77 statement line consists of 80 character positions or columns, numbered 1 through 80 that are divided into 4 fields.

The **-W132** compiler option may be used to expand the statement field to column 132.

<u>Field</u>	<u>Columns</u>
Statement label	1-5
Continuation	6
Statement	7-72
	7-132 (using -W132 compiler option)
Identification	73-80
	132+ (using -W132 compiler option)

The Identification field is available for any purpose the programmer may desire and is ignored by the Fortran compiler. Historically this field has been used for sequence numbers and commentary. The statement line itself may exceed the column of the last field; the compiler ignores all characters beyond the last field.

There are four types of source lines in Fortran:

Comment Line – used for source program annotation and formatting. A comment line may be placed anywhere in the source program and assumes one of the forms:

- Column 1 contains the character C or an asterisk. The remainder of the line is ignored by the compiler.
- Column 1 contains an exclamation point. The remainder of the line is ignored by the compiler.
- The line is completely blank.
- An exclamation point not contained within a character constant designates all characters including the exclamation point through the end of the line to be commentary.
- Column 1 contains the character D, d, X, or x and the conditional compilation **-X** compiler option is not on.

Comment lines have no effect on the object program and are ignored by the Fortran compiler.

End Line – the last line of a program unit.

- The word `END` must appear within the statement field.
- Each Fortran program unit must have an `END` line as its last line to inform the compiler that it is at the physical end of the program unit.
- An `END` line may follow any other type of line.

Initial Line – the first and possibly only line of each statement.

- Columns 1 through 5 may contain a statement label to identify the statement.
- Column 6 must contain a zero or a blank.
- Statement field contains all or part of the statement.

Continuation Line – used when additional characters are required to complete a statement originating on an initial line.

- Columns 1 through 5 must be blank.
- Column 6 must contain a character other than zero or blank.
- Statement field contains the continuation of the statement.
- There may be only 99 continuation lines per statement, for a total of 100 lines per statement.

Fortran 90 Free Format

A Fortran 90 free format statement line consists of 132 character positions. In this source format, there are no “fields” in which labels, statements, or comments must appear.

A statement label must appear before the statement on a line; it may be in *any* column:

```
100 I=123
J=456
200 I=123
      300      I=123
400
      I=123
```

Comments in Fortran 90 format begin with an exclamation point character “!” in any column not in character context. The letter C in column 1 does not indicate a comment.

```
! This entire line is a comment
A=1 !A trailing comment
      ! Blank line
C="ab!cd"!The exclamation point in quotes does not begin a comment
```

To continue a statement across multiple lines, the ampersand character (&) is used according to the following rules:

- The “&” as the *last* non-blank character on a line signifies the line is continued on the next line. Comment lines may not be continued. A comment, beginning with “!”, may appear after the “&” when not in character context.
- The “&” as the *first* non-blank character on the next line will cause continuation to begin after the “&”. Otherwise, continuation begins with the first character. When continuing character context, the next line *must* begin with a "&" as the first non-blank character.

The following valid program demonstrates Fortran 90 continuation:

```
! Fortran 90 example
character s,&
      t,&
      &u
s="This string &
  &contains NO &
  &ampersand symbols" !Comment
t="One ampersand:&&
  &"
      1  &
      0      0 I=1 !This line has label 100
```

VAX FORTRAN Tab-Format

A VAX FORTRAN tab-format statement line consists of 80 character positions or columns with fields similar to those in the Fortran format. The TAB character is used to begin the continuation and statement fields rather than having them tied to a specific column. The tab-format is primarily useful for entering FORTRAN source with many editors since it is generally easier to hit the TAB key once as opposed to hitting the space bar multiple times before a statement. A TAB character elsewhere in a FORTRAN statement is treated as spaces. Tab-format may be freely mixed with fixed format source.

A statement label must appear anywhere on a line before the first TAB character:

```
1 (TAB) WRITE(*,*) "This line has label 1"  
  (TAB) WRITE(*,*) "No label on this line"  
1  2  3 (TAB) WRITE(*,*) "This line has label 123"
```

Comments in VAX FORTRAN tab-format begin with a C or asterisk in column 1 or an exclamation point character “!” in any column not in character context. Having a D or X in column 1 will also comment an entire line unless the **-x** compiler option is on for conditional compilation:

```
! Full-line comment  
(TAB) I=123 ! Statement begins after TAB  
D      J=456 ! Compiled only with x option
```

To continue a statement across multiple lines, the continuation line must have a non-zero digit after the first tab. Note that the initial line can not start with a digit – no FORTRAN statement begins with a digit:

```
(TAB) WRITE(*,*) "This line spans  
(TAB) 1multiple lines because  
(TAB) 2 of the non-zero continuation digit after first  
(TAB) 3 tab character on each line"
```

The **-W132** compiler option will expand the statement field to column 132.

Multiple Statement Lines

Multiple statements may be placed on the same line by separating them with a semicolon (;).

```
I=10; J=10; N(I,J)=0
```

Statement Order

PROGRAM, FUNCTION, SUBROUTINE, BLOCK DATA or MODULE		
USE		
FORMAT and ENTRY	IMPLICIT NONE	
	PARAMETER	IMPLICIT
	PARAMETER and DATA	Derived-Type definitions, Interface Blocks, Type Declaration statements, statement function statements, and specification statements
	DATA	Executable Statements
CONTAINS		
Internal or module procedures		
END		

Required Statement Order

INCLUDE Statement

This statement is a compiler directive and is provided as a convenience for copying standard declaration statements and documentation sections directly into a source file at compile time. The syntax of this statement is:

```
INCLUDE filespec
```

where: *filespec* is a standard file specification presented as a character constant (i.e. enclosed in quotation marks or apostrophes).

INCLUDE statements may be nested up to 10 files deep.

The **-I** compiler option, described in the chapter **Using the Compilers** in the *Pro Fortran User Guide*, is useful for specifying directories and search paths for include files that may reside in directories other than the current one.

Conditional Compilation Statements

In addition to the previously described limited capability for conditional compilation available by placing a D or an X in column one, a complete set of compiler directives is also provided which gives dynamic control over the compilation process. These compiler directives are specified with a dollar sign (\$) in column 1 and take the following forms:

```
$DEFINE name [value]
$UNDEFINE name
```

```
$IF expr
$ELSE
$ELIF expr
$ENDIF
```

name is the *case sensitive* symbolic name of a variable that is used only in conditional compilation directives. It can have the same name as any variable used in standard FORTRAN statements without conflict. Conditional compilation variables exist from the point they are defined until the end of the file unless they are undefined with the `$UNDEFINE` directive. *value* is an integer constant expression that is used to give the variable a value. If *value* is not present, the variable is given the value of 1.

expr is any expression using constants and conditional compilation variables which results in a logical value. Also provided is the logical function `DEFINED` which is used to determine if a variable has actually been defined. Consider the following:

```
$IF DEFINED(debug)
    WRITE (*,*) "iter=",iter
$ENDIF
```

In this case, you are interested in displaying the value of the variable `iter` only during the debugging stages of program development. To turn this feature on, all that is required is to define `debug` before the conditional compilation clause in the source file:

```
$DEFINE debug
```

A more complicated example:

```
$DEFINE precision 8

$IF precision == 4
    REAL a,b,c,d(100),pi
    pi = atan(1.0)*4.0
$ELIF precision == 8
    DOUBLE PRECISION a,b,c,d(100),pi
    pi = datan(1d0)*4d0
$ENDIF
```

Conditional compilation variables that are not defined can only be referenced as arguments to the `DEFINED` function. Any other use will result in a compile error.

Inline comments are *not* allowed.

Conditional compilation statements are particularly useful for managing large groups of include files with nested dependencies. Suppose you are using an include file named "graphics.inc" that declares certain structures which are dependent on another include file named "types.inc". If you add the statement `$DEFINE TYPES` at the end of the "types.inc" include file and add the following three statements to the beginning of the "graphics.inc" include file:

```
$IF !DEFINED(TYPES)
    INCLUDE "types.inc"
$ENDIF
```

your source program file only needs to include "graphics.inc" to compile successfully.

The conditional compilation statements are:

<code>\$DEFINE variable [value]</code>	define a variable [with a <i>value</i>]
<code>\$UNDEFINE variable</code>	undefined a variable
<code>\$IF expression</code>	begin an <i>if</i> clause
<code>\$ELSE</code>	begin an <i>else</i> clause
<code>\$ELIF expression</code>	begin an <i>else if</i> clause
<code>\$ENDIF</code>	end an <i>if</i> clause

The conditional compilation operators are:

<code><</code>	less than
<code><=</code>	less than or equal
<code>==</code>	equal
<code>!=</code>	unequal
<code>></code>	greater than
<code>>=</code>	greater than or equal
<code>!</code>	logical <i>not</i>
<code>&&</code>	logical <i>and</i>
<code> </code>	logical <i>or</i>

TYPE AND KIND

Fortran provides several categories of data known as *type*. These are integers, floating-point numbers, complex numbers, character, and logical values. Integers are an exact representation of integral values. Floating-point numbers are approximations of real numbers. Complex numbers are composed of two floating-point numbers representing the real and imaginary portions of the value. Character values are representations of individual or strings of printable characters. Logical data items represent the Boolean values of true and false. The representation and presentation of these data types are described in detail in the following sections of this chapter.

Fortran further provides for data of the same *type* to support multiple precision, range, and size or length. The numeric model is known as *kind*. Several features are available for inquiring about the numeric model and specifying the kind of the data entity. They are:

KIND(<i>x</i>)	<i>x</i> is a numeric expression.
SELECTED_INT_KIND(<i>p</i>)	<i>p</i> is an integer expression.
SELECTED_REAL_KIND(<i>p</i> , <i>r</i>)	<i>p</i> and <i>r</i> are integer expressions

These functions return an integer value that in the Absoft implementation of Fortran represents the number of bytes required to store a value specified by the expression. The value of the expression *p* represents the number of required digits of precision. The value of the expression *r* represents the number of required digits of precision. If the value cannot be represented, the functions return a value of -1. Examples:

Function	Value
KIND(1.0)	4
KIND(32873)	4
SELECTED_INT_KIND(3)	2
SELECTED_INT_KIND(5)	4
SELECTED_INT_KIND(12)	8
SELECTED_REAL_KIND(6,30)	4
SELECTED_REAL_KIND(14,100)	8
SELECTED_REAL_KIND(30,300)	16

DATA ITEMS

The symbolic name used to represent a constant, variable, array, substring, statement function, derived type, or external function identifies its data type, and once established,

it does not change within a particular program unit. The data type of an array element name is always the same as the type associated with the array.

Special FORTRAN statements, called type statements, may be used to specify a data type as character, logical, integer, real, double precision, or complex. When a type statement is not used to explicitly establish a type, the first letter of the name is used to determine the type. If the first letter is I, J, K, L, M, N, i, j, k, l, m, or n, the type is integer; any other letter yields an implied type of real. The `IMPLICIT` statement, described later, may be used to change the default implied types.

The `IMPLICIT NONE` statement, also described later, causes the compiler to require the declaration of all variables.

An intrinsic function, `LOG`, `EXP`, `SQRT`, `INT`, etc., may be used with either a specific name or generic name. The data types of the specific intrinsic function names are given in the **Programs, Subroutines, and Functions** chapter. A generic function assumes the data type of its arguments as discussed in that chapter.

A main program, subroutine, common block, module, and block data subprogram are all identified with symbolic names, but have no data type.

Constants

Fortran constants are identified explicitly by stating their actual value; they do not change in value during program execution. The plus (+) character is not required for positive constants. The value of zero is neither positive nor negative; a zero with a sign is just zero.

The data type of a constant is determined by the specific sequence of characters used to form the constant. A constant may be given a symbolic name with the `PARAMETER` statement.

For fixed format source programs, except within character and Hollerith constants, blanks are not significant and may be used to increase legibility. For example, the following forms are equivalent:

3.14159265358979	3.1415 92653 58979
2.71828182845904	2.7182 81828 45904

Blanks are significant in a free format source program and may not occur within a numeric or logical constant.

Character Constant

A character constant is a string of ASCII characters delimited by either apostrophes (') or quotation marks ("). The character used to delimit the string may be part of the string itself by representing it with two successive delimiting characters. The number of charac-

ters in the string determines the length of the character constant. A character constant requires a character storage unit (one byte) for each character in the string.

"TEST"	'TEST'
"EVERY GOOD BOY"	'EVERY GOOD BOY'
"Luck is everything"	'Luck is everything'
"didn't"	'didn't'

As an extension to Fortran, special escape sequences may be embedded in a character constant by using the backslash (\) followed immediately by one of the letters in the following list. The actual character value generated in place of the escape sequence is system dependent. For compatibility with FORTRAN programs which do not expect the backslash as an escape sequence, these escape sequences are not recognized by the compiler unless the **-YCSLASH=1** option is used.

<u>Escape Sequence</u>	<u>Meaning</u>
\n	Newline
\t	Tab
\r	Carriage return
\f	Form feed
\b	Backspace
\\	Backslash
\nnn	Sets character position with value <i>nnn</i> , where <i>nnn</i> are octal digits.

For example,

```
WRITE(*,*) "First line\nSecond line"
```

When compiled without the **- YCSLASH=1** option, it displays,

```
First line\nSecond line
```

When compiled with the **- YCSLASH=1** option, it displays,

```
First line
Second line
```

Logical Constant

Logical constants are formed with the strings of characters, `.TRUE.` and `.FALSE.`, representing the Boolean values true and false respectively. A false value is represented with the value zero, and a true value is represented with the value one. A default logical constant requires one numeric storage unit (four bytes).

Integer Constant

An integer constant is an exact binary representation of an integer value with negative integers maintained in two's complement form. An integer constant is a string of decimal digits that may contain a leading sign

```
15
101
-72
1126
123456789
```

The default range of an integer constant is -2147483648 to +2147483647. This is internally represented using four bytes of memory. One, two, and eight byte integer constants are available by attaching a *kind* parameter to the end of the constant:

```
22_1
367_2
54893657452854_8
-8746359852145_8
```

The range of an one-byte integer constant is -128 to +127. The range of an two-byte integer constant is -32768 to +32767. The range of an eight-byte integer constant is -9223372036854775808 to +9223372036854775807.

The *kind* parameter can be represented symbolically:

```
INTEGER, PARAMETER :: I2=SELECTED_INT_KIND(3)
J = 224_I2
```

Alternate Integer Bases

The compiler normally expects all numeric constants to be in base ten, however, three alternate unsigned integer bases are available when explicitly specified. These optional bases are binary, octal, and hexadecimal and are designated by preceding the constant with the characters B, O, and Z respectively and delimiting the constant itself with apostrophes. The following examples all result in the assignment of the decimal value 3994575:

```
I = B'1111001111001111001111'
J = O'17171717'
K = Z'3CF3CF'
```

The VAX FORTRAN form of hexadecimal and octal constants may also be used:

```
J = '017171717'O
K = '3CF3CF'X
```

Real Constant

A real constant consists of an optional sign and a string of digits that contains a decimal point. The decimal point separates the integer part of the constant from the fractional part and may be placed before or after the string indicating that either the integer or fractional part is zero. A real constant may have an exponent that specifies a power of ten applied to the constant. An exponent is appended to a real constant with the letter E, D, or Q and an integer constant. The exponent letters, E, D, or Q, indicate the precision of the constant: single, double, and quad precision respectively. If an exponent is given and the fractional part is zero, the decimal point may be omitted.

<u>Constant</u>	<u>Value</u>
1E2	100.0
-12.76	-12.76
1.07D-1	.107
0.4237E3	423.7
7.892Q2	789.2

Single precision values are maintained in IEEE single precision floating point representation. The exponent range is -37 to +39. The most significant bit is interpreted as the sign, the next eight bits provide a binary exponent biased by 127, and the remaining twenty-three bits form the binary mantissa with a twenty-fourth bit implied. This representation supplies seven digits of precision and a range of $\pm 0.3402823\text{E}+39$ to $\pm 0.1175494\text{E}-37$.

Double precision values are maintained in IEEE double precision floating point representation. The exponent range is -307 to +309. The most significant bit is interpreted as the sign, the next eleven bits provide a binary exponent biased by 1023, and the remaining fifty-two bits form the binary mantissa with a fifty-third bit implied. This representation yields sixteen digits of precision and a range of $\pm 0.1797693134862320\text{D}+309$ to $\pm 0.2225073858507202\text{D}-307$.

Quad precision values are maintained as a pair IEEE double precision floating point values, with the most significant value representing the exponent and the most significant portion of the mantissa and least significant value representing the least significant portion of the mantissa and least. The exponent range is -307 to +309. The most significant bit is interpreted as the sign, the next eleven bits provide a binary exponent biased by 1023, and the remaining fifty-two bits of both values form the binary mantissa. This representation yields thirty-one digits of precision and a range of $\pm 0.179769313486231570814527423731730\text{Q}+309$ to $\pm 0.222507385850720229569787989021279\text{Q}-307$.

Real constants may also be qualified with a *kind* parameter:

```
1.0_4  
33.7_8  
-0.7193_16
```

The *kind* parameter can be represented symbolically:

```
INTEGER, PARAMETER :: DP=SELECTED_REAL_KIND(15,100)
A = 3.0_DP
```

Complex Constant

A complex constant is stated using a left parenthesis, a pair of real or integer constants separated by a comma, and a right parenthesis. The first constant is the real portion (in the mathematical sense) and the second is the imaginary portion. A complex constant requires two numeric storage units (eight bytes).

<u>Constant</u>	<u>Value</u>
(2.76, -3.81)	= 2.76 -3.81 <i>i</i>
(-12, 15)	= -12.0 +15.0 <i>i</i>
(0.62E2, -0.22E-1)	= 62.0 -.022 <i>i</i>

Hollerith Constant

The Hollerith data type is an older method of representing characters in FORTRAN. While it is not included in the current standard, this implementation of FORTRAN includes the Hollerith data type to provide compatibility for older programs. Like character constants, a Hollerith constant is formed with a string of any of the characters from the ASCII character set. Logical, integer, real, double precision, and complex variables can be defined with a Hollerith value through `DATA` statements and `READ` statements.

A Hollerith constant is stated with a nonzero, unsigned integer constant, the letter H, and a string of characters whose length must be the same as the integer constant.

```
4HTEST
14HEVERY GOOD BOY
```

When a Hollerith constant is assigned to a variable it is left justified and space padded if the length of the constant is less than the length of the variable.

If a Hollerith constant appears anywhere in the source code except within a `DATA` statement, a `FORMAT` statement, or a `CALL` statement, an error will result. Embedded escape sequences (i.e. `\n`) are not permitted in a Hollerith constant.

Variables

A variable is used to maintain a Fortran quantity and is associated with a single storage location through a symbolic name. Simple variables are often called scalar variables to distinguish them from arrays and array elements. Arrays are discussed in the next chapter. Unlike a constant, the value of a variable can be changed during the execution of a program with assignment statements and input and output statements.

Substrings

A substring is a contiguous segment of a character entity and is itself a character data type. It can be used as the destination of an assignment statement or as an operand in an expression. Either a character variable or character array element can be qualified with a substring name:

```
v( [e1] : [e2] )  
a(s [,s]...)( [e1] : [e2] )
```

where: *e1* and *e2* are called substring expressions and must have integer values.

v is the symbolic name of a character variable, and *a(s [,s]...)* is the name of a character array element (see the **Arrays** chapter).

The values *e1* and *e2* specify the leftmost and rightmost positions of the substring. The substring consists of all of the characters between these two positions, inclusive. For example, if *A* is a character variable with a value of 'ABCDEF', then *A(3:5)* would have a value of 'CDE'.

The value of the substring expression *e1* must be greater than or equal to one, and if omitted implies a value of one. The value of the substring expression *e2* must be greater than or equal to *e1* and less than or equal to the length of the character entity, and if omitted implies the length of the character entity.

Substring expressions may contain array or function references. The evaluation of a function within a substring expression must not alter the value of other entities also occurring within the substring expression.

STORAGE

Storage refers to the physical computer memory where variables and arrays are stored. Variables and arrays can be made to share the same storage locations through equivalences, common block declarations, and subprogram argument lists. Data items that share storage in this manner are said to be associated.

The contents of variables and arrays are either defined or undefined. All variables and arrays not initially defined through **DATA** statements are undefined.

A storage unit is primarily a FORTRAN 77 concept and refers to the amount of storage needed to record a particular class of data. A storage unit can be a numeric storage unit or a character storage unit.

Numeric Storage Unit

A numeric storage unit can be used to hold or store an integer, real, or logical datum. One numeric storage unit consists of four bytes. The amount of storage for default numeric data is as follows:

<u>Data Type</u>	<u>Storage</u>
Integer	1 storage unit
Real	1 storage unit
Double precision	2 storage units
Complex	2 storage units
Logical	1 storage unit

Character Storage Unit

A character datum is a string of characters. The string may consist of any sequence of ASCII characters. The length of a character datum is the number of characters in the string. A character storage unit differs from numeric storage units in that one character storage unit is equal to one byte and holds or stores one character.

Storage Sequence

The storage sequence refers to the sequence of storage units, whether they are held in memory or stored on external media such as a disk or a tape.

Storage Association

The storage locations of variables and arrays become associated in the following ways:

- The `EQUIVALENCE` statement (described in the **Specification and DATA Statements** chapter) causes the storage units of the variables and array elements listed within the enclosing parentheses to be shared. Note that the data types of the associated entities need not be the same.
- The variable and array names appearing in the `COMMON` statements (described in the **Specification and DATA Statements** chapter) of two different program units are associated.
- The dummy arguments of subroutine and function subprograms are associated with the actual arguments in the referencing program unit.
- An `ENTRY` statement (described in the **Programs, Subroutines, and Functions** chapter) in a function subprogram causes its corresponding name to be associated with the name appearing in the `FUNCTION` statement.

Storage Definition

Storage becomes defined through `DATA` statements, assignment statements, and I/O statements. `READ` statements cause the items in their associated I/O lists to become defined. Any I/O statement can cause items in its parameter list to become defined (the `IOSTAT` variable for instance). A `DO` variable becomes defined as part of the loop initialization process.

The fact that storage can become undefined at all should be carefully noted. Some events that cause storage to become undefined are obvious: starting execution of a program that does not initially define all of its variables (through `DATA` statements), attempting to read past the end of a file, and executing an `INQUIRE` statement on a file that does not exist. When two variables of different types are either partially or totally associated, defining one causes the other to become undefined.

Because Fortran provides for both dynamic as well as static storage allocation, certain events can cause dynamically allocated storage to become undefined. In particular, returning from subroutine and function subprograms causes all of their variables to become undefined except for those:

- in blank `COMMON`.
- specified in a `MODULE`
- specified in `SAVE` statements.

The **-s** compiler option has the effect of an implicit `SAVE` for every program unit encountered during the current compilation (see the chapter **Using the Compilers** in the *Pro Fortran User Guide*).

CHAPTER 3

Specification and DATA Statements

Specification statements are used to define the properties of the symbolic entities, variables, arrays, symbolic constants, etc. that are used within a program unit. For this reason, specification statements are also called declaration statements and are grouped together in the declaration section of a program unit: before any statement function statements, `DATA` statements, and executable statements. Specification statements themselves are classified as nonexecutable.

`DATA` statements are used to establish initial values for the variables and arrays used within a Fortran program. Variables *not* appearing in `DATA` statements may contain random values when a program starts executing. The use of undefined variables can cause problems that are difficult to detect when transporting a program from one environment to another, because the previous environment may have set all storage to zeros while the new environment performs no such housekeeping.

TYPE STATEMENTS

The most common of the specification statements are the type statements. They are used to give data types to symbol names and declare array names. Once a data type has been associated with a symbol name it remains the same for all occurrences of that name throughout a program unit.

Arithmetic and Logical Type Statements

The forms of the type statement for the arithmetic and logical data types are:

```
type  v [,v]...
type [*len] v[/value/] [,v[/value/]]...
type [(kind)] [[attributes] ::] v [,v]... [=value]
```

where: `type` can be any of the following specifiers: `LOGICAL`, `INTEGER`, `REAL`, `DOUBLE PRECISION`, `COMPLEX`, or `DOUBLE COMPLEX`.

`v` is the symbolic name of a variable, an array, a constant, a function, a dummy procedure, or an array declaration.

`len` is an unsigned integer constant that specifies the length, in bytes, of a variable, an array element, a symbolic constant, or a function.

value is an optional initial value for the preceding variable or array. When initializing an array, *value* must contain constants separated by commas for each element of the array.

kind is a kind expression that specifies the kind of the data entity (see below).

attributes is a list attributes that apply to the data entity (see below).

The following *len* specifiers are available:

- `LOGICAL*4` is the default for `LOGICAL` and occupies one numeric storage unit. The default may be changed to `LOGICAL*2` with the **-in** compiler option (see the chapter **Using the Compilers** in the *Pro Fortran User Guide*).
- `LOGICAL*2` data is a representation of the logical values of true and false. This type of logical data occupies one half of one numeric storage unit. A false value is represented by the number zero and a true value is represented by the number one.
- `LOGICAL*1` data is a representation of the logical values of true and false. This type of logical data occupies one byte. A false value is represented by the number zero and a true value is represented by the number one.
- `INTEGER*8` data is an exact binary representation of an integer in the range of -9223372036854775808 to +9223372036854775807 with negative integers carried in two's complement form. This type of integer is maintained in two numeric storage units.
- `INTEGER*4` is the default for `INTEGER` and occupies one numeric storage unit. The default may be changed to `INTEGER*2` or `INTEGER*8` with the **-in** compiler option (see the chapter **Using the Compilers** in the *Pro Fortran User Guide*).
- `INTEGER*2` data is an exact binary representation of an integer in the range of -32768 to +32767 with negative integers carried in two's complement form. This type of integer is maintained in one half of one numeric storage unit.
- `INTEGER*1` data is an exact binary representation of an integer in the range of -128 to +127 with negative integers carried in two's complement form. This type of integer is maintained in one byte of storage.

- `REAL*4` is the default for `REAL` and occupies one numeric storage unit. The default may be changed to `REAL*8` with the **-N113** compiler option (see the chapter **Using the Compilers** in the *Pro Fortran User Guide*).
- `REAL*8` data is identical to `DOUBLE PRECISION` and occupies two numeric storage units.
- `REAL*16` is quad precision and occupies 4 numeric storage units
- `COMPLEX*8` data is identical to `COMPLEX` and occupies two numeric storage units. The default may be changed to `COMPLEX*16` with the **-N113** compiler option (see the chapter **Using the Compilers** in the *Pro Fortran User Guide*).
- `COMPLEX*16` data is similar to `COMPLEX` except that both halves of the complex value are represented as `DOUBLE PRECISION` and it occupies four numeric storage units.
- `COMPLEX*32` data is similar to `COMPLEX` except that both halves of the complex value are represented as `REAL*16` and it occupies eight numeric storage units.

attributes consists of comma separated list of one or more of the following:

PARAMETER	allows a constant to be given a symbolic name. The symbol must be given a value.
ALLOCATABLE	specifies that the array will have a deferred shape that will be specified when it is allocated.
DIMENSION	is given with an array dimension declaration to be applied to the variable name(s) given.
EXTERNAL	allows symbolic names to be used as arguments in <code>CALL</code> statements and function references without the compiler automatically creating a variable at the point of reference.
INTENT(<i>inout</i>)	specifies the intended use of a dummy argument. <i>inout</i> may be one of <code>IN</code> , <code>OUT</code> , <code>INOUT</code> .
INTRINSIC	allows the specific or generic name of an intrinsic function to be used as an argument in <code>CALL</code> statements and function references without the compiler automatically creating a variable at the point of reference.
OPTIONAL	specifies that the declared dummy argument is optional and may be omitted from the actual argument list of a subroutine or function reference.

POINTER	specifies that the variable will be a pointer.
SAVE	prevents variables and arrays that are declared locally in subprograms from being deallocated and losing their definition status when the program is exited.
TARGET	allows the variable to be associated via a pointer assignment operator with a variable that has the POINTER attribute.
VALUE	specifies that the declared dummy argument is passed by value rather than the default of by reference.
VOLATILE	informs the compiler that variable can be modified outside of Fortran and it should not be maintained in a CPU register.
BIND(<i>spec</i>)	specifies that the entity has interoperability with C and external linkage. <i>spec</i> takes the form: C [,NAME= <i>character_constant</i>] where: <i>character_constant</i> is the external name of the entity.

kind examples:

```
REAL(4)
REAL(KIND(1.0D0))
INTEGER(SELECTED_INT_KIND(4))
```

Character Type Statement

The form of the type statement for the character data type is:

```
CHARACTER [*len [,]] v[*len] [,v[*len]]...
CHARACTER [(len)] [attributes] [::] v [,v]... [=value]
CHARACTER [*len [,]] v[*len] [/value/] [,v[*len] [/value/]]...
```

where: *v* is a variable name, an array name, an array declaration, the symbolic name of a constant, a function name, or a dummy procedure name

len is either an unsigned INTEGER constant, an INTEGER constant expression within parentheses, or an asterisk within parentheses and specifies the length, in bytes, of a variable, an array element, a symbolic constant, or a function.

value is an optional initial value for the preceding variable or array. When initializing an array, *value* must contain constants separated by commas for each element of the array.

If *len* directly follows the word CHARACTER, the length specification applies to all symbols not qualified by their own length specifications. When *len* is not specified directly after the keyword CHARACTER, all symbols not qualified by their own length specifications default to one byte.

The length of symbolic CHARACTER constants, dummy arguments of SUBROUTINE and FUNCTION subprograms, and CHARACTER functions may be given as an asterisk enclosed in parentheses: (*). The length of a symbolic constant declared in this manner is the number of characters appearing in the associated PARAMETER statement. Dummy arguments and functions assume the length of the actual argument declared by the referencing program unit.

```
CHARACTER TITLE*(*)
PARAMETER (TITLE = 'FORTRAN 77')
```

or:

```
CHARACTER(LEN=*), PARAMETER :: TITLE = 'Fortran 90'
```

produces a ten byte symbolic CHARACTER constant.

DERIVED TYPES

Derived types are useful for manipulating and maintaining data objects that are most suitably organized as an aggregate. Derived types are also known as *user defined data types*. A derived type must first be defined. Once defined, instances of the derived type can be declared with unique variable names.

Derived type definition:

```
TYPE name
  component_declarations
END TYPE [name]
```

where: *name* is the symbolic name that will be used to reference the type.

component_declarations declarations of the variables, arrays, and derived types that comprise the new type.

Examples:

```
TYPE DATE
  INTEGER Month
  INTEGER Day
  INTEGER Year
END TYPE DATE
```

```
TYPE POINT
  INTEGER X, Y
END TYPE POINT

TYPE TRIANGLE
  TYPE (POINT) A, B, C
END TYPE TRIANGLE
```

Once a derived type has been defined, it is available to declare variables of that type and to create values of that type. A derived type declarations takes a form similar to normal type statement:

```
TYPE(type_name) [attributes [::]] v [, v]... [=value]
```

where: *type_name* is the name of a previously defined type.

v is the symbolic name of a variable, an array, or an array declaration.

value is a type constant (see below).

Examples:

```
TYPE (DATE) :: DATEA, DATEB
TYPE (TRIANGLE), DIMENSION(10) :: T1, T2, T3
```

Derived Type Values

A derived type value takes the form of the type name and a comma separated list of expressions that define the components of the type. Examples:

```
TYPE (DATE) :: DATEC = DATE(5, 12, 2001)
TYPE (TRIANGLE) :: T1 = TRIANGLE (POINT(6,2), POINT(6,14), POINT(18,2))

DATEA = DATE(2, 16, 1977)
```

Derived Type Component Reference

The components of a derived type are accessed with the variable name and the component separated by a percent sign (%):

```
TYPE (DATE) :: DateA
TYPE (TRIANGLE) :: T1
```

```
DateA%Month = 7
DateA%Day   = 12
DateA%Year  = 2002
```

```
T1%A%X = -12
T1%A%Y = 4
T1%B%X = 15
T1%B%Y = 22
T1%C%X = 15
T1%C%Y = 4
```

Normal array element syntax is used to access arrays of derived types:

```
TYPE (DATE), DIMENSION (5) :: Dates

IF (Dates(i)%Month == Dates(j)%Month .AND. &
    Dates(i)%Day == Dates(j)%Day .AND. &
    Dates(i)%Year == Dates(j)%Year) THEN
```

The ability to define operators for manipulating derived types and their components is provided in Fortran. This is discussed on the Chapter **Modules**.

POINTERS

A pointer is an object that can be made to point to other objects. If the object that a pointer points to is not itself a pointer, it must have the `TARGET` attribute. The pointer assignment operator, `=>`, is used to *associate* a pointer to an object it is important to distinguish the difference between pointer assignment and normal assignment.

```
REAL, TARGET :: A, B
REAL, POINTER :: P

IF (I > 10) THEN
    P => A
ELSE
    P => B
END IF

P = 1.0/P
```

A powerful use of pointers is to create linked lists.

```
TYPE Style
  INTEGER index
  REAL value
  TYPE(Style), POINTER :: next
END TYPE Style

TYPE(Style), POINTER :: Head, Current, Next

ALLOCATE(Head)
Head = Style(1, 0.0, NULL())
```

allocate a linked list of 10 elements:

```
Current => Head
do i=2, 10
  ALLOCATE(Current%next)
  Current => Current%next
  Current = Style(i, 0.0, NULL())
end do
```

deallocate a linked list:

```
Current => Head
do
  if (.not. ASSOCIATED(Current)) exit
  Next => Current%next
  DEALLOCATE(Current)
  Current => Next
end do
```

Pointer Aliases

A pointer can point to a commonly used array section to simplify a program.

```
INTEGER, DIMENSION(3,4), TARGET :: a
INTEGER, DIMENSION(:, :), POINTER :: b

a = RESHAPE((/1,2,3,4,5,6,7,8,9,10,11,12/), (/3,4/))

b => a(1:3,2:3)
print *,b

end

4  5  6  7  8  9
```

Arrays of Pointers

Arrays of pointers are not allowed in Fortran, but the equivalent effect can be easily attained with a type containing a pointer element.

```

TYPE POINTER_ARRAY
  REAL, POINTER, DIMENSION(:) :: A
END TYPE POINTER_ARRAY

TYPE(POINTER_ARRAY) :: DIMENSION(10) :: S

DO I=1,10
  ALLOCATE(S(I)%A(100))
END DO

```

ASSOCIATED() Function

The logical function `ASSOCIATED` is used to determine if a pointer is associated with a target. It is also used to determine if a pointer is associated with a specific target.

```
ASSOCIATED(pointer[, target])
```

NULL() Function

The `NULL` function is used to give a pointer a disassociated status.

```

REAL, POINTER :: P => NULL()

P => NULL()

```

NULLIFY Statement

The `NULLIFY` statement is used to disassociate a pointer.

```

REAL, POINTER :: P
...
NULLIFY(P)

```

is equivalent to:

```
P => NULL()
```

ALLOCATABLE STATEMENT

The `ALLOCATABLE` statement specifies the `ALLOCATABLE` attribute for a list of variable names:

```
ALLOCATABLE [::] var[ (def-spec) ] [, var[ (def-spec) ] ]...
```

where `var` is the symbolic name of a variable

`def-spec` is a deferred shape specification if the `DIMENSION` attribute had been previously specified for the variable

DIMENSION STATEMENT

The `DIMENSION` statement declares the names and supplies the dimension information for arrays to be used within a program unit.

```
DIMENSION [::] a(d) [, a(d) ] ...
```

where `a(d)` is an array declarator as described in the chapter **Arrays**.

Arrays may be declared with either `DIMENSION` statements, `COMMON` statements, or type statements, but multiple declarations are not allowed. That is, once a symbolic name has been declared to be an array it may not appear in any other declaration statement with an array declarator in the same program unit. The following three statements declare the same array:

```
DIMENSION A(5,5,5)
REAL A(5,5,5)
REAL(KIND(1.0e0), DIMENSION(5,5,5)) :: A
REAL(KIND(1.0e0)) :: A(5,5,5)
COMMON A(5,5,5)
```

COMMON STATEMENT

The `COMMON` statement is used to declare the storage order of variables and arrays in a consistent and predictable manner. This is done through a FORTRAN data structure called a common block, which is a contiguous block of storage. A common block may be identified by a symbolic name but does not have a data type. Once the order of storage in a common block has been established, any program unit that declares the same common block can reference the data stored there without having to pass symbol names through argument lists.

The `GLOBAL` statement may be used to make the common block accessible to other tasks on systems which support shared data.

Common blocks are specified in the following manner:

```
COMMON [/[cb]/] nlist [[,]/[cb]/ nlist]...
GLOBAL [/[cb]/] nlist [[,]/[cb]/ nlist]...
```

where: *cb* is the symbolic name of the common block. If *cb* is omitted, the first pair of slashes may also be omitted.

nlist contains the symbolic names of variables, arrays, and array declarators.

When the `COMMON` block name is omitted, the `COMMON` block is called blank `COMMON`. The symbolic name "BLANK" is reserved by the compiler for blank `COMMON` and if used explicitly as a `COMMON` block name will result in all entities in the *nlist* being placed in blank `COMMON`.

Any `COMMON` block name or an omitted name (blank `COMMON`) can occur more than once in the `COMMON` statements in a program unit. The list of variables and arrays following each successive appearance of the same common block name is treated as a continuation of the list for that common block name.

A `COMMON` block name can be the same as that of a variable, array, or program unit.

EQUIVALENCE STATEMENT

The `EQUIVALENCE` statement provides a means for one or more variables to share the same storage location. Variables that share storage in this manner are said to be associated. The association may be total if both variables are the same size or partial if they are of different sizes. The `EQUIVALENCE` statement is used in the following manner:

```
EQUIVALENCE (nlist) [, (nlist)]...
```

The symbolic names of at least two variables, arrays, array elements, or character substrings must be specified in each *nlist*. Only integer constant expressions may be used in subscript and substring expressions. An array name unqualified by a subscript implies the first element of the array.

An `EQUIVALENCE` statement causes storage for all items in an individual *nlist* to be allocated at the same starting location:

```
REAL A, B
INTEGER I, J
EQUIVALENCE (A, B), (I, J)
```

The variables `A` and `B` share the same storage location and are totally associated. The variables `I` and `J` share the same storage location and are totally associated.

Items that are equivalenced can be of different data types and have different lengths. When a storage association is established in this manner several elements of one data type may occupy the same storage as one element of a different data type:

```
DOUBLE PRECISION D
INTEGER I(2)
EQUIVALENCE (D,I)
```

The array element $\mathbb{I}(1)$ shares the same storage location as the upper (most significant) thirty-two bits of \mathbb{D} , and the array element $\mathbb{I}(2)$ shares the same storage location as the lower (least significant) thirty-two bits of \mathbb{D} . Because only a portion of \mathbb{D} is stored in the same location as $\mathbb{I}(1)$, these entities are only partially associated.

The EQUIVALENCE may not specify that an item occupy more than one storage location or that a gap occur between consecutive array elements.

Equivalence of Arrays

The EQUIVALENCE statement can be used to cause the storage locations of arrays to become either partially or totally associated.

```

REAL A(8),B(8)
INTEGER I(5),J(7)
EQUIVALENCE (A(3),B(1)), (A(1),I(1)), (I(4),J(1))

```

Storage would be allocated as follows:

Equivalence of Substrings

The EQUIVALENCE statement can be used to cause the storage locations of substrings to become either partially or totally associated.

```

CHARACTER A(2)*5
CHARACTER B*8
EQUIVALENCE (A(2)(2:4),B(4:7))

```

Byte storage would be allocated as follows:

Notice that the lengths of the equivalenced substrings need not be the same, as in the above example.

COMMON and EQUIVALENCE Restrictions

The `EQUIVALENCE` statement can be used to increase the size of a common block by adding storage to the end, but it cannot increase the size by adding storage units prior to the first item in a `COMMON` block.

The `EQUIVALENCE` statement must not cause two different `COMMON` blocks to have their storage associated.

CONTAINS STATEMENT

The `CONTAINS` statement marks the section of program unit (MAIN, SUBROUTINE, FUNCTION, or MODULE) that contains internal procedures. See the Chapter **PROGRAMS, SUBROUTINES, and FUNCTIONS**. Example

```
CONTAINS
```

EXTERNAL STATEMENT

The `EXTERNAL` statement allows symbolic names to be used as arguments in `CALL` statements and function references without the compiler automatically creating a variable at the point of reference. Symbolic names so declared may or may not have an associated data type. The `EXTERNAL` statement is given with a list of external or dummy procedure names or intrinsic function names:

```
EXTERNAL proc [,proc]...
```

where: *proc* is a symbolic name of a procedure or intrinsic function.

An intrinsic function name appearing in an `EXTERNAL` statement specifies that the particular intrinsic function has been replaced by a user supplied routine.

IMPLICIT STATEMENT

The `IMPLICIT` statement is used to establish implicit data typing that differs from the default `INTEGER` and `REAL` typing described in chapter **The Fortran Program**. The `IMPLICIT` statement can also be used to remove implied typing altogether. The `IMPLICIT` statement takes the following form:

```
IMPLICIT type [*len] (a [,a]...) [,type [*len] (a [,a]...)]...
```

where: *type* is a type chosen from the set `CHARACTER`, `LOGICAL`, `INTEGER`, `REAL`, `DOUBLE PRECISION`, `COMPLEX`, `DOUBLE COMPLEX`, or `NONE`.

len is an unsigned integer constant specifying the length, in bytes, of `LOGICAL`, `INTEGER`, `REAL`, `COMPLEX` or `CHARACTER` variables.

a is an alphabetic specifier which is either a single letter or a range of letters. A range of letters is specified with a character representing the lower bound of the range, a minus, and a character representing the upper bound of the range. The range A-z specifies all the letters of the alphabet.

If *len* is not specified, the defaults are:

CHARACTER	1 byte
LOGICAL	4 bytes
INTEGER	4 bytes
REAL	4 bytes
COMPLEX	8 bytes

The `IMPLICIT` statement must appear before all other declaration statements except `PARAMETER` statements and specifies the data type of all symbolic names that can take a data type that are not given one explicitly with a type statement. The data type will be the data type that corresponds to the first character of their names.

When `NONE` appears in place of a type specifier, all variables used within the program unit must appear in an explicit type statement.

INTENT STATEMENT

The `INTENT` statement specifies the `INTENT` attribute for a list of dummy arguments. It is used to inform the compiler how dummy arguments are intended to be used. `INTENT (IN)`, `INTENT (OUT)`, and `INTENT (INOUT)` are available.

```
INTENT(spec) [::] var [,var...]
```

where *spec* is `IN`, `OUT`, or `INOUT`.

var is the symbolic name of a function or subroutine dummy argument.

```
SUBROUTINE SOLVER(TD)
  IMPLICIT NONE
  REAL, INTENT(IN) :: TD
  ...
END SUBROUTINE SOLVER
```

INTRINSIC STATEMENT

The `INTRINSIC` statement designates symbolic names as intrinsic functions (see the chapter **Programs, Subroutines, and Functions**). Similar to the `EXTERNAL` statement, this allows intrinsic functions to be used as arguments in `CALL` statements and function references without the compiler automatically creating a variable at the point of

reference. The intrinsic function name specified in an `INTRINSIC` statement retains its associated data type. The `INTRINSIC` statement is given in the following manner:

```
INTRINSIC func [,func]...
```

where: *func* is the name of an intrinsic function.

The following intrinsic functions do not follow conventional FORTRAN calling conventions and may not appear in an `INTRINSIC` statement:

AMAX0	LEN
AMAX1	LGE
AMIN0	LGT
AMIN1	LLE
CHAR	LLT
CMPLX	MAX
DBLE	MAX0
DCMPLX	MAX1
DMAX1	MIN
FLOAT	MIN0
ICHAR	MIN1
IDINT	REAL
IFIX	SNGL
INT	
DFLOATI	IIFIX
DFLOATJ	IINT
FLOATI	JIDINT
FLOATJ	JIFIX
HFIX	JINT
IIDINT	

This restriction also applies to the Absoft Fortran 77 intrinsic functions below:

ADJUSTL	VAL2
ADJUSTR	VAL4
TRIM	[%]LOC
REPEAT	[%]VAL

The `INTRINSIC` statement is used to pass intrinsic functions to external procedures:

```

INTRINSIC SIN,COS
DIMENSION A(100),B(100)
CALL TRIG(SIN,A)
CALL TRIG(COS,B)
END

SUBROUTINE TRIG(FUNC,ARRAY)
DIMENSION ARRAY(100)
DO 10 I=1,100
10  ARRAY(I) = FUNC(FLOAT(I))
END
```

NAMelist STATEMENT

The `NAMelist` statement associates a unique group name with a list of variable or array names. The group-name is used in namelist directed input and output operations. Namelists are specified in the following manner:

```
NAMelist /group_name/nlist[[,]/group_name/nlist]...
```

where: *group_name* is a symbolic name.

nlist is a list of variables or array names that is to be associated
with *group_name*

The *group_name* must be a unique identifier and cannot be used for any purpose other than namelist directed I/O in the program unit in which it appears.

Variables in a namelist can be of any data type and can be explicitly or implicitly typed. Subscripted array names and `CHARACTER` substrings cannot appear in the `NAMelist`, however `NAMelist` directed I/O can be used to assign values to array elements and `CHARACTER` substrings.

The order of appearance of variables in a `NAMelist` controls the order in which the values are written during `NAMelist` directed output. The order of appearance has no affect on `NAMelist` directed input.

Adjustable arrays are not permitted in `NAMelist` statements.

OPTIONAL STATEMENT

The `OPTIONAL` statement specifies the `OPTIONAL` attribute for a list of dummy arguments:

```
OPTIONAL [::] var [,var...]
```

where *var* is the symbolic name of a function or subroutine dummy argument.

```
INTERFACE
  REAL FUNCTION Accumulate(A, B, C)
    REAL :: A
    REAL, OPTIONAL :: B, C
  END FUNCTION Accumulate
END INTERFACE

D = Accumulate(X,Y,Z)
D = Accumulate(X,B=Y)
D = Accumulate(X,C=Z)
```

The `PRESENT` function is used to determine if an *optional* dummy argument is present.

```
REAL FUNCTION Accumulate(A, B, C)
  REAL :: A
  REAL, OPTIONAL :: B, C
```

```

Accumulate = A
IF (PRESENT(B)) Accumulate = Accumulate + B
IF (PRESENT(C)) Accumulate = Accumulate + C
END FUNCTION Accumulate

```

PARAMETER STATEMENT

The `PARAMETER` statement allows a constant to be given a symbolic name in the following manner:

```
PARAMETER (p=c [,p=c]...)
```

where p is the symbolic name that is used to reference the constant and c is a constant expression.

If the data type and length attributes of the symbolic name are to be other than the implied default for that name, then the type (and size) must be previously defined in an explicit type statement or through the typing supplied by an `IMPLICIT` statement. A character parameter may have its length declared as an asterisk in parentheses, in which case the actual size will be the number of characters in the expression.

The type of the constant expression must match the type of the symbolic name.

```

INTEGER EOF
CHARACTER TITLE*(*)
PARAMETER (PI=3.1415926, THIRD=1.0/3.0)
PARAMETER (EOF=-1)
PARAMETER (TITLE='FORTRAN 77')

```

POINTER STATEMENT

The `POINTER` statement specifies the `POINTER` attribute for a list of variable names:

```
POINTER [::] var[(def-spec)] [,var[(def-spec)]]...
```

where var is the symbolic name of a variable

$def-spec$ is a deferred shape specification if the `DIMENSION` attribute had been previously specified for the variable

POINTER STATEMENT (CRAY-STYLE)

The `POINTER` statement is an extension to standard Fortran and is provided for compatibility with older implementations of Fortran. This type of pointer is commonly known as a “Cray pointer”. It is recommended that new programs use the standard pointer mechanism described earlier in this chapter.

The `POINTER` statement is used to establish a means for directly manipulating the address of a variable. Normally, when a FORTRAN variable is created, either explicitly with a

declaration statement of implicitly by reference in the program, its location or address in memory is fixed by the compiler or the linker. However, there are situations where it is useful for the location of a variable to be dynamic. The `POINTER` statement provides this mechanism by associating a pointer to a variable as follows:

```
POINTER (ptr,pbv) [, (ptr, pbv),...]
```

where: *ptr* is the symbolic name that is used to manipulate the address of the associated variable and *pbv* is the pointer-based variable.

Before the pointer-based variable can be used, the pointer must be defined with the initial address of the variable. The `LOC` function is useful for this purpose:

```
INTEGER m(100), a
POINTER (pa, a)

pa = LOC(m)
DO i=1, 100
    a = i
    pa = pa + 4
END DO
```

The array will contain the integers from 1 to 100 after the execution of the `DO` loop.

When a pointer-based variable is referenced, its address is established from the current value of the associated pointer variable. Pointers can be used just as if they were `INTEGER` variables except that they cannot appear as dummy arguments. Pointer-based variables can be of any FORTRAN data type. Pointer-based variables cannot be dummy arguments or appear in `COMMON`, `GLOBAL`, `EQUIVALENCE`, `NAMelist`, `SAVE`, `VALUE` or `PARAMETER` statements. Further information and examples are presented in the appendices.

PRIVATE AND PUBLIC STATEMENTS

Modules allow specifications, data, and procedures to be encapsulated. The default is that all data entities are visible to procedures that use the module; they are `PUBLIC`. Often it is useful to limit the accessibility of symbolic entities to the module itself. For example, only the generic interface to a generic function is typically visible outside of the module. The specific interfaces and function implementations are *private* to the module. A `PRIVATE` statement can be used limit the scope to only the module.

```
REAL, PARAMETER, PRIVATE :: PI=3.1415926535

PRIVATE :: SP_LOGB, DP_LOGB

TYPE SEMAPHORE
  PRIVATE
  REAL, DIMENSION(), POINTER :: ACCESS
  LOGICAL STATE
END TYPE SEMAPHORE
```

RECORD STATEMENT

RECORD statements are used to define variables that are instances of structures defined in STRUCTURE declarations. Variables declared in RECORD statements are composite or aggregate data items. RECORD statements are defined as follows:

```
RECORD /structure-name/rlist[/structure-name/rlist...]
```

where: *structure-name* is a name given in a STRUCTURE definition.

rlist is one or more variable names, array names or array declarators separated by commas.

Record names cannot appear in NAMELIST statements and can only be read from and written to UNFORMATTED files. For more information on the use of records, see the appendices.

SAVE STATEMENT

Fortran permits dynamic as well as static storage allocation. Variables, arrays, and COMMON blocks declared in a main program are allocated statically and always retain their definition status. Variables and arrays that are declared locally in subprograms are allocated dynamically when the subprogram is invoked. When the subprogram executes a RETURN or END statement, these items are deallocated and lose their definition status. The SAVE statement is used to retain the definition status of these items by specifying them in the following manner:

```
SAVE [[::] a [,a]...]
```

where: *a* is either a common block name delimited with slashes, a variable name, or an array name.

If *a* is not specified, the effect is as though all items in the program unit were presented in the list.

In order to maintain portability in FORTRAN programs, it is recommended that the SAVE statement be used on COMMON blocks declared only in subprograms. Although it has no effect in this implementation, other FORTRAN compilers may cause deallocation of common blocks upon returning from a subprogram if they are not SAVED.

SEQUENCE STATEMENT

The storage sequence of members of a derived type is not specified. For optimization purposes, a compiler may rearrange them. The `SEQUENCE` statement is used specify the order of the derived type members and to assure adjacency.

```
TYPE PIXEL
  SEQUENCE
    INTEGER(SELECTED_INT_KIND(4)) :: XPos, YPos
    INTEGER(SELECTED_INT_KIND(9)) :: RVal, GVal, BVal
END TYPE PIXEL
```

STRUCTURE DECLARATION

The `STRUCTURE` statement is an extension to standard Fortran and is provided for compatibility with older implementations of Fortran. It is recommended that new programs use the standard derived type mechanism described earlier in this chapter.

The `STRUCTURE` declaration provides a mechanism for organizing various data items into meaningful groups forming an aggregate data type called a structure. The `STRUCTURE` declaration establishes the data types, ordering, and alignment of a structure, but may not actually define storage for a structure. Storage for the actual structure may be defined in the `STRUCTURE` declaration or with a `RECORD` statement (see above section **RECORD Statement**). A `STRUCTURE` declaration takes the following form:

```
STRUCTURE [/structure-name/][rlist [,rlist...]]
  field-declaration
  [field-declaration]
  .
  .
  .
  [field-declaration]
END STRUCTURE
```

where: *structure-name* is the name used to identify the structure declaration.

rlist is a list of symbolic names or array declarators allocating records having the form defined in the `STRUCTURE` declaration.

field-declaration defines a data item in the structure.

The *structure-name* must be unique among `STRUCTURE` declarations, but can be used for variable and global names.

A *field-declaration* can be any FORTRAN type statement, a `POINTER` declaration, a `UNION` declaration, a `RECORD` statement, or another `STRUCTURE` declaration. Arithmetic and logical type statements may take an optional `/value/` specifier to provide initialization for the data item in each instance of the structure as described earlier in this chapter.

The name `%FILL` can be used in place of the symbol name in a *field-declaration*. (e.g `INTEGER*2 %FILL`). In this case, no field name is defined, but empty space is added to the structure for the purpose of alignment. This extension is provided for compatibility with other FORTRAN environments.

If the *field-declaration* is another `STRUCTURE` declaration, the *structure-name* may be omitted, but the *rlist* must be given. In this case the symbolic names in *rlist* become fields of the structure which contains it. If the *structure-name* is given, it can be used in `RECORD` statements to define instances of the substructure.

The structure fields established with field-declarations are accessed by appending a period and the field name to the record name:

```
STRUCTURE /date/ day
    INTEGER mm
    INTEGER dd
    INTEGER yy
END STRUCTURE

day.mm = 9
day.dd = 12
day.yy = 90
```

See the appendix **Using Structures and Pointers** for examples using `STRUCTURE` declarations.

UNION DECLARATION

A `UNION` declaration defines a data area which is shared by one or more fields or groups of fields. It begins with a `UNION` statement and ends with an `ENDUNION` statement. In between are `MAP` and `ENDMAP` statements which define the field or groups of fields which will share the storage area. A `UNION` declaration is as follows:

```
UNION
    map-declaration
    map-declaration
    [map-declaration]
    .
    .
    .
    [map-declaration]
END UNION
```

where: *map-declaration* takes the following form:

```
MAP
    field-declaration
    [field-declaration]
    .
    .
    .
    [field-declaration]
END MAP
```

A *field-declaration* contains one or more of the following, a **STRUCTURE** declaration, a **POINTER** declaration, another **UNION** declaration, a **RECORD** statement or a standard FORTRAN type declaration. Field-declarations cannot have been previously declared or be dummy arguments.

The size of the shared data area for the union is the size of the largest map area contained within the union. The fields of only one of the map areas are defined at any given time during program execution.

Example:

```
UNION
    MAP
        INTEGER*4 long
    END MAP
    MAP
        INTEGER*2 short1, short2
    END MAP
END UNION
```

In the above example, the storage for the first half of the field `long` is shared by the field `short1`, and the storage for the second half of the field `long` is shared by the field `short2`.

TARGET STATEMENT

The **TARGET** statement specifies the **TARGET** attribute for a list of variable names:

```
TARGET [::] var[(array-decl)] [,var[(array-decl)]]...
```

where *var* is the symbolic name of a variable

array-decl is an array declaration.

VALUE STATEMENT

The `VALUE` statement informs the compiler that certain dummy arguments are going to be passed by value to a subroutine or function. When a value parameter is passed, the contents of a variable rather than its address is passed. The result is that the actual argument cannot be changed by the program unit. Pass by value is the default method for C and Pascal programs and is used when the `VAL` intrinsic function is used in Absoft Fortran 77.

```
VALUE [::] a [[,a]...]
```

where: *a* is the name of a dummy argument.

Value arguments can be of any data type except `CHARACTER`. Value arguments cannot be arrays, but they can be of type `RECORD`. `VALUE` statements cannot appear in program units which contain `ENTRY` statements.

VOLATILE STATEMENT

The `VOLATILE` statement disables optimization for any symbol, array, or `COMMON` block. It is useful when a variable is actually an absolute address, when two dummy arguments can represent the same location, or when a `POINTER` variable points to defined storage.

```
VOLATILE [::] a [[,a]...]
```

where: *a* is either a common block name delimited with slashes, a variable name, or an array name.

DATA STATEMENT

Variables, substrings, arrays, and array elements are given initial values with `DATA` statements. `DATA` statements may appear only after the declaration statements in the program unit in which they appear. `DATA` statements take the following form:

```
DATA vlist/clist/ [[,] vlist/clist/]...
```

where: *vlist* contains the symbolic names of variables, arrays, array elements, substrings, and implied `DO` lists

clist contains the constants which will be used to provide the initial values for the items in *vlist*

A constant may be specified in *clist* with an optional repeat specifier: a positive integer constant (or symbolic name of a constant) followed by an asterisk. The repeat specifier is used to indicate one or more occurrences of the same constant:

```
DATA A,B,C,D,E/1.0,1.0,1.0,1.0,1.0/
```

can be written as:

```
DATA A,B,C,D,E/5*1.0/
```

An array name unqualified by a subscript implies every element in the array:

```
INTEGER M(5)  
DATA M/5*0/
```

means:

```
INTEGER M(5)  
DATA M(1),M(2),M(3),M(4),M(5)/0,0,0,0,0/
```

Type conversion is automatically performed for arithmetic constants (INTEGER, REAL, DOUBLE PRECISION, and COMPLEX) when the data type of the corresponding item in *vlist* is different. CHARACTER constants are either truncated or padded with spaces when the length of the corresponding character item in *vlist* is either shorter or longer than the constant respectively.

The items specified in *vlist* may not be dummy arguments, functions, or items in blank COMMON. Items in a named common block can be initialized only within a BLOCK DATA subprogram (see the chapter **Programs, Subroutines, and Functions**).

Implied DO List In A DATA Statement

An implied DO list is used to initialize array elements as though the assignments were within a DO loop. The implied DO list is of the form:

(dlist, i = m1, m2 [,m3])

where: *dlist* contains array elements and implied DO lists

i is the DO variable and must be an integer

m1, *m2*, and *m3* are integer constant expressions which establish the initial value, limit value, and increment value respectively (see the **Control Statements** chapter)

```

INTEGER M(10,10),N(10),L(4)
CHARACTER*3 S(5)

DATA (N(I),I=1,10),((M(I,J),J=3,8),I=3,8)/5*1,5*2,36*99/
DATA (L(I),I=1,4)/'ABCD','EFGH','IJKL','MNOP'/
DATA (S(I),I=1,5)/'ABC','DEF','GHI','JKL','MNO'/

```

CHAPTER 4

Arrays

ARRAYS

An array is compound data object that consists of a sequence of data elements all of the same type and referenced by one symbolic name. When an array name is used alone it refers to the entire sequence starting with the first element. When an array name is qualified by a subscript it refers to an individual element of the sequence. Arrays can be statically declared or dynamically declared (allocatable).

ARRAY DECLARATOR

An array declarator is used to assign a symbolic name to an array, define its data type (either implicitly or explicitly), and declare its dimension information:

$$a(d [, d] \dots)$$

where a is the symbolic name that will be used to reference the array and the elements of the array, and d is called a dimension declarator. An array declarator must contain at least one and no more than seven dimension declarators. A dimension declarator is given with either one or two arguments:

$$[d1:] d2$$

where $d1$ and $d2$ are called the lower and upper dimension bounds respectively. The lower and upper dimension bounds must be expressions containing only constants or integer variables. Integer variables are used only to define adjustable and automatic arrays (described below) in subroutine and function subprograms. If the lower dimension bound is not specified, it has a default value of one.

An array declarator specifies the *rank* and *shape* of an array. The number of dimensions is determined by the number of dimension declarators and called its *rank*. Dimension bounds specify the size or extent of an individual dimension. The sequence of dimension extents of an array is called its *shape*.

REAL A(10,10,10)	! rank 3, shape (10,10,10)
REAL B(2,12,8,8)	! rank 4, shape (2,12,8,8)
REAL C(-10:-1,2:11,-2:7)	! rank 3, shape (10,10,10)

While the value of a dimension bound may be positive, negative, or even zero, the value of the lower dimension bound must always be less than or equal to the value of the upper

dimension bound. The extent of each dimension is defined as $d_2 - d_1 + 1$. The number of elements in an array is equal to the product of all of its dimension extents.

Array declarators are called constant, adjustable, automatic, deferred shape, or assumed shape depending on the form of the dimension bounds. A constant array declarator must have integer constant expressions for all dimension bounds. An adjustable array declarator contains one or more integer variables in the expressions used for its bounds. An automatic array is an explicit shape array in a subprogram that takes its dimension bounds and hence its shape in non-constant expressions.

An array declarator in which the upper bound of the last dimension is an asterisk (*) is an assumed size array declarator. Adjustable and assumed size array declarators may appear only in subroutine and function subprograms.

All array declarators are permitted in `DIMENSION` and type statements, however only constant array declarators are allowed in `COMMON` or `SAVE` statements.

An array can be either an actual array or a dummy array. An actual array uses constant array declarators and has storage established for it in the program unit in which it is declared. A dummy array may use constant, adjustable, or assumed size array declarators and declares an array that is associated through a subroutine or function subprogram dummy argument list with an actual array.

The number of dimensions and the dimension extents of arrays associated with one another either through common blocks, equivalences, or dummy argument lists need not match.

ARRAY SUBSCRIPT

The individual elements of an array are referenced by qualifying the array name with a subscript:

$$a(s_1, s_2, \dots)$$

where each s in the subscript is called a subscript expression and a is the symbolic name of the array. The subscript expressions are integer scalar expressions whose values fall between the lower and upper bounds of the corresponding dimension. There must be a subscript expression for each declared dimension.

Subscript expressions may contain array element and function references. The evaluation of a subscript expression must not affect the value of any other expression in the subscript. This means that functions should not have side effects altering the values of the other subscript expressions.

Note the following example where A is a two-dimensional array and F is an external function.

$Y = A(X, F(X))$

The function $F(X)$ will be evaluated before the value of x is fetched from memory. Therefore, if $F(X)$ alters the value of x , the altered value will be used as the first subscript expression.

Arrays are stored in contiguous array element order. Fortran arrays are stored in *column major* order. The ordering of elements in the array $A(5,4)$ is:

The order of an array element within the column major storage sequence of the array in memory is called the subscript value. This is calculated according to the following table:

Number of Dimensions	Dimension Declarator	Subscript	Subscript Value
1	(j1:k1)	(s1)	$1 + (s1 - j1)$
2	(j1:k1, j2:k2)	(s1, s2)	$1 + (s1 - j1) + (s2 - j2) * d1$
3	(j1:k1, j2:k2, j3:k3)	(s1, s2, s3)	$1 + (s1 - j1) + (s2 - j2) * d1$
.	.	.	.
.	.	.	.
.	.	.	.
n	(j1:k1, ..., jn:kn)	(s1, ..., sn)	$1 + (s1 - j1) + (s2 - j2) * d1$ $+ (s3 - j3) * d2 * d1 + \dots$ $+ (sn - jn) * dn - 1 * dn - 2$ $* \dots * d1$

where: $d_i = k_i - j_{i+1} + 1$

Subscript Value

Note that subscript values always range from 1 to the size of the array:

`DIMENSION X(-4:4), Y(5,5)`

`X(3) = Y(2,4)`

For the array element name $x(3)$, the subscript is (3), the subscript expression is 3 with a value of three, and the subscript value is eight. For the array element name $y(2,4)$, the subscript is (2,4), the subscript expressions are 2 and 4 with values two and four, respectively, and the subscript value is seventeen. The effect of the assignment statement is to replace the eighth element of x with the seventeenth element of y .

ARRAY VALUED EXPRESSIONS

Some FORTRAN constructs accept array names unqualified by a subscript. This means that every element in the array is selected. The elements are processed in column major order. The first element is specified with subscript expressions all equal to their lower dimension bounds. The next element will have the leftmost subscript expression increased by one. After an array subscript expression has been increased through its entire extent it is returned to the lower bound and the next subscript expression to the right is increased by one.

When an array name is used unqualified by a subscript, it implies that every element in the array is to be selected as described above. Generally speaking, any Fortran 90 expression may have array operands and the result is array valued. For example:

```
REAL, DIMENSION(200,300) :: A, B, C
A = 0.0
C = A+B
```

Array names unqualified by a subscript may also be used in `COMMON` statements for data alignment and sharing purposes, in actual and dummy argument lists to pass entire arrays to other procedures, in `EQUIVALENCE` statements where it implies the first element of the array, and in `DATA` statements for giving every element an initial value. Array names may also be used in the input and output statements to specify internal files, format specifications and elements of input and output lists.

ASSUMED SHAPE ARRAY

An assumed shape array is a subprogram dummy argument declaration where the dimension bounds are omitted. The array *assumes* its shape from the actual argument. Note that only the shape is assumed, not the lower and upper bounds.

```
REAL, DIMENSION(0:10,10:10) :: A           ! actual argument
REAL, DIMENSION(:, :) :: D                 ! dummy argument
```

The equivalent explicit shape declaration is:

```
REAL, DIMENSION(1:11,1:11) :: A           ! dummy argument
```

AUTOMATIC ARRAY

An automatic shape array is an explicit shape array in a subprogram that takes its dimension bounds and hence its shape from non-constant expressions. Such an array is local to the subprogram, allocated on the stack on entry, and deallocated on exit.

```
SUBROUTINE SWAP(A,B)
REAL, DIMENSION(:)      :: A,B           ! assumed shape arrays
REAL, DIMENSION(SIZE(A)) :: TEMP         ! automatic array
TEMP = A
A     = B
B     = TEMP
END SUBROUTINE SWAP
```

DEFERRED SHAPE ARRAY

A deferred shape or allocatable array is an array that has an `ALLOCATABLE` attribute and a specified rank. However, the bounds are determined when storage is created for the array in an `ALLOCATE` statement. Allocatable arrays are freed with the `DEALLOCATE` statement,

```
REAL, DIMENSION(:, :), ALLOCATABLE :: A
...
ALLOCATE(A(2:12), (4:14))
...
DEALLOCATE(A)
```

The `ALLOCATE` and `DEALLOCATE` statements may take the optional specifier `STAT=ierr`. *ierr* is an `INTEGER` variable that is defined with a 0 if the allocation succeeds. If the allocation fails, *ierr* is defined with one of the following integer values:

10004	attempt to allocate array of requested size failed
10045	attempt to <code>DEALLOCATE</code> unallocated array
10046	attempt to <code>DEALLOCATE</code> item with modified size
10047	attempt to <code>ALLOCATE</code> array which has already been allocated
10070	attempt to <code>ALLOCATE</code> unassociated pointer

```
ALLOCATE(A(2:12), (4:14), STAT=ierr)
```

The syntax of the `ALLOCATE` statement is:

```
ALLOCTATE (object_list [STAT=ierr])
```

where *object_list* is a comma separated list of an array declarators.

ierr is a scalar integer variable.

The syntax of the `DEALLOCATE` statement is:

```
DEALLOCTATE (object_list [STAT=ierr])
```

where *object_list* is a comma separated list of allocatable array names.

`ierr` is a scalar integer variable.

POINTER ARRAYS

Pointer arrays are similar to allocatable arrays in that they are explicitly allocated with the `ALLOCATE` statement to have computed sizes and are explicitly deallocated with the `DEALLOCATE` statement. Simple examples of pointer arrays result by replacing `ALLOCATABLE` with `POINTER` in the preceding examples of allocatable arrays.

```
REAL, DIMENSION(:, :), POINTER :: A
...
IF (.NOT. ASSOCIATED(A)) ALLOCATE(A(2:12, 4:14), STAT=IERR)
...
DEALLOCATE(A, STAT=IERR)
```

In addition, pointer arrays can be used as *aliases* for (may *point to*) other arrays and array sections; the pointer assignment statement is used to establish such aliases. The target for pointer associations (as such aliasing is called) may be other explicitly allocated arrays, or static or automatic arrays that have been explicitly identified as allowable targets for pointers. The association status of a pointer array may be tested with the `ASSOCIATED` intrinsic function. Pointer arrays may be dummy arguments and structure components, neither of which are allowed for allocatable arrays.

Given this apparent similarity between allocatable arrays and pointer arrays, what is the fundamental distinction between these two forms of dynamic arrays, and when should allocatable arrays be used rather than pointer arrays? Pointer arrays subsume all of the functionality of allocatable arrays, and in this sense allocatable arrays are never needed - pointer arrays could always suffice. The problem with pointer arrays is efficiency. Though pointer arrays must always point to explicit *targets*, which makes some optimization practical that would otherwise be infeasible, pointer assignment makes optimization of pointer arrays much more difficult than for allocatable arrays. Because of their more limited nature and functionality, allocatable arrays are just “simpler” and can be expected to be more efficient than pointer arrays.

Therefore, when all that is needed is simple dynamic allocation and deallocation of arrays, and automatic arrays are not sufficient, use allocatable arrays. A common example of this is if a “work array” is needed of a size dependent upon the results of a local computation. If, on the other hand, the algorithm calls for a dynamic alias, of for example a “moving” section of a host array, then a pointer array is probably indicated.

ARRAY SECTIONS

Array section subscript syntax, called a *subscript triplet*, provides a means to access a subarray:

$[lower-bound]:[upper-bound]:[stride]$

Any element of the triplet can be omitted. If *lower-bound* is omitted, the default is the actual lower bound. If *upper-bound* is omitted, the default is the actual upper bound. If *stride* is omitted, the default is 1. Examples:

```
A(I, J:N)           ! elements J-N of row I
A(I, :)             ! all elements of row I
A(I, : 1:N:3)       ! elements 1, 4, ..., through N of row I
```

Array Sections

INTEGER, DIMENSION(5,5) :: m													
		1	6	11	16	21			1	6	11	16	21
		2	7	12	17	22			2	7	12	17	22
m(3,4)		3	8	13	18	23		m(3,3:5)	3	8	13	18	23
		4	9	14	19	24			4	9	14	19	24
		5	10	15	20	25			5	10	15	20	25
		1	6	11	16	21			1	6	11	16	21
		2	7	12	17	22			2	7	12	17	22
m(:,3)		3	8	13	18	23		m(1::2,2:4)	3	8	13	18	23
		4	9	14	19	24			4	9	14	19	24
		5	10	15	20	25			5	10	15	20	25

ARRAY CONSTRUCTOR

Array constructors are used to create general rank-one arrays (vectors). The vector consists an opening parenthesis, forward slash, the list of array elements, a forward slash, and a closing parenthesis. The array elements can be constants, expressions, or implied DO lists.

```
      (/1, 2, 3, 4, 5, 6, 7, 8, 9, 10/)
or:
      (/ (i, i=1,10) /)
```

```
      (/2, 4, 6, 8, 10, 12, 14, 16, 18, 20/)
or:
      (/ (i, i=2,20,2) /)
```

```
      (/1, 2, 3, 1, 2, 3, 1, 2, 3/)
or:
      (/ ((i, i=1,3), j=1,3) /)
```

```
      (/0, 1, 0, 1, 0, 1, 0, 1, 0, 1/)
or:
      (/ (0,1, i=1,5) /)
```

```
INTEGER, DIMENSION(10) :: M, N
M = (/ (0,1 i=1,5) /)
N = (/ (M+1) /)
```

VECTOR SUBSCRIPT

A form of section subscript syntax, call a vector subscript, provides access to individual array elements:

```
A( (/1, 8, 6, 5/) )
```

Produces a section with the elements $A(1)$, $A(8)$, $A(6)$, and $A(5)$.

```
A( (/1, 8, 6, 5/) ) = (/ -1, -1, -1, -1/)
```

Example:

```
REAL, DIMENSION(5,2) :: A
A(:,1) = (/1.,2.,3.,4.,5./)
A(:,2) = (/6.,7.,8.,9.,10./)
PRINT *, A((/1,3,5/),1)
PRINT *, A((/1,3,5/),2)
END

1.00000  3.00000  5.00000
6.00000  8.00000 10.00000
```

ARRAY CONFORMANCE

Two arrays of the same shape are said to be conformable. Array assignments can only be performed when both the left and right hand sides are conformable. The `RESHAPE` function is available to change the shape of an array.

```
REAL, DIMENSION(2,3) :: A
REAL, DIMENSION(3,2) :: B

A = (/1.,2.,3.,4.,5.,6./)      ! produces an error
B = A                          ! produces an error

A = RESHAPE((/1.,2.,3.,4.,5.,6./), (/2,3/))
B = RESHAPE(A, (/3,2/))
```

ARRAY OPERATIONS

Most operations that can be performed on scalar variables can be performed on arrays.

```
REAL, DIMENSION(2,3) :: A,B
```

$$\begin{array}{lcl} A = \begin{bmatrix} 2 & 3 & 5 \\ 1 & 7 & 4 \end{bmatrix} & B = \begin{bmatrix} 5 & 4 & 1 \\ 2 & 2 & 3 \end{bmatrix} & 2 = \begin{bmatrix} 2 & 2 & 2 \\ 2 & 2 & 2 \end{bmatrix} \\ \\ A+B = \begin{bmatrix} 7 & 7 & 6 \\ 3 & 9 & 7 \end{bmatrix} & A*B = \begin{bmatrix} 10 & 12 & 5 \\ 2 & 14 & 12 \end{bmatrix} & \\ \\ A+2 = \begin{bmatrix} 4 & 5 & 7 \\ 3 & 9 & 6 \end{bmatrix} & A*2 = \begin{bmatrix} 4 & 6 & 10 \\ 2 & 14 & 8 \end{bmatrix} & \end{array}$$

```
REAL, DIMENSION(2,3) :: A, B, C
```

```
A = 0.0  
B = (B+1.0)/2.0  
C = SQRT(B)
```

ARRAY VALUED FUNCTIONS

A function may return an array. However, whenever such a function is referenced it must always have an explicit interface.

```
FUNCTION VADD(a, r)  
REAL, DIMENSION(:) :: a  
REAL r  
REAL, DIMENSION(SIZE(a)) :: VADD  
VADD = a+COS(r)  
RETURN  
END
```

CHAPTER 5

Modules and Interfaces

A module is a Fortran program unit that encapsulates global declarations, global data, derived types and procedures. A module is not executable. It contains definitions to be used by other programs unit and these definitions may include procedures, but the module itself is not executable.

An interface provides an explicit prototype of a procedure.

MODULES

Module entities are made available to other program units by the `USE` statement:

```
program Seismic_Processing
  use Seismic_Trace_Definitions
  ...
end program
```

Available modules entities are said to be “use associated” within the using program. A module may contain *private* entities; such entities are not available to using program units (private entities are available only within the module itself, including any procedure definitions within the module). In addition, the *only* form of the use statement limits the module entities that are available in the using program unit.

The principal contents of a module include: type definitions, interface definitions, procedure definitions, and shared data objects (including global constants). Typical uses of modules include: procedure libraries (with explicit interfaces), encapsulated data abstractions, and shared-data units (alternative to `COMMON`)

Module Structure

The general structure of a module is as follows; additional syntax rules are listed for specific items in the following description:

```
module module-name
  use-statements
  constant-definitions
  variable-declarations
  interface-blocks
  type-definitions
contains
  module-subprograms
end module [module-name]
```

Module Use

Other program units (main programs, functions, subroutines, and other modules) may use the definitions provided in a module by including a `USE` statement immediately after the program unit heading, as in the `Seismic_Processing` example above:

```
use module-name [rename-list]
use module-name, only: only-list
```

In the first example, all public entities of the module are imported. In the second example, only the specified public entities are imported.

Module entities are imported into the using program with the same name as they have in the module, unless they are renamed in the `USE` statement; this may be necessary to avoid name conflicts, as an imported (“use associated”) name does not “mask” a local entity with the same name. A *rename* has the form:

```
local-name => use-name
```

where *local-name* is the new name (in the using program) and *use-name* is the name of the entity in the module (the new name “points to” the module entity). An *only* can be either the name of the module entity being imported, or a rename:

```
[ local-name => ] use-name
```

PRIVATE And PUBLIC Statements

Modules allow specifications, data, and procedures to be encapsulated. The default is that all data entities are visible to procedures that use the module; they are `PUBLIC`. Often it is useful to limit the accessibility of symbolic entities to the module itself. For example, only the generic interface to a generic function is typically visible outside of the module. The specific interfaces and function implementations are *private* to the module. A `PRIVATE` statement can be used to limit the scope to only the module.

```
REAL, PARAMETER, PRIVATE :: PI=3.1415926535

PRIVATE :: SP_LOGB, DP_LOGB

TYPE SEMAPHORE
  PRIVATE
  REAL, DIMENSION(), POINTER :: ACCESS
  LOGICAL STATE
END TYPE SEMAPHORE
```

INTERFACES

A procedure interface comprises the information needed to use that procedure correctly; explicit interfaces make this information available to the calling environment. *Interface blocks are used to provide various explicit interfaces.* Explicit interfaces include dummy argument list characteristics, alternate names for a procedure (primarily used to define procedure overloads - that is, generic procedures), and new operator and assignment definitions. Interface blocks are not

needed to make module and internal procedure interfaces explicit, as these interfaces are automatically explicit wherever such procedures are accessible. However, external procedure interfaces are not automatically explicit; interface blocks with one or more interface bodies may be used to make them explicit:

```
interface
  interface-body
  [interface-body] ...
end interface
```

Each *interface-body* specifies an external (or dummy) procedure name, its type (if it is a function), and the order names, and types (and kinds) of all dummy arguments. If a function has certain properties it may be given an *operator interface*, thereby creating a *defined operator*, and called using operator notation; it must have one (unary operator) or two (binary operator) intent(in) arguments. Such a function may be called with either the normal function syntax or infix operation format; in the latter form the first actual argument appears as the first operation operand and the second actual argument is the second operand (for unary operators the operand follows the operator). The operator form of the interface block is used to define a new operator and associate it with one (or more) functions:

```
interface operator (defined-operator)
  [interface-body] ...
  [module-procedure-stmt] ...
end interface
```

Examples of using an operator interface to define an overloaded operators are:

```
interface operator (+)
  integer function sum_char_int(c, i)
    character :: c
    integer :: i
  end function
end interface
```

and:

```
MODULE DATES

TYPE DATE
  INTEGER Month, Day, Year
END TYPE DATE

INTERFACE OPERATOR(==)
  MODULE PROCEDURE DatesEqual
END INTERFACE

PRIVATE DatesEqual

CONTAINS

LOGICAL FUNCTION DatesEqual(A, B)
  TYPE(DATE), INTENT(IN) :: A, B
  IF ((A%Month == B%Month) .AND. &
      (A%Day == B%Day) .AND. &
      (A%Year == B%Year)) THEN
    DatesEqual = .TRUE.
  END IF
END FUNCTION DatesEqual
```

```
        ELSE
            DatesEqual = .FALSE.
        ENDIF
    END FUNCTION DatesEqual

END MODULE DATES

PROGRAM Main

USE DATES

TYPE (DATE) :: A = DATE(2,10,2002)
TYPE (DATE) :: B = DATE(2,11,2002)

IF (A == B) PRINT *, "Equal"

END PROGRAM Main
```

A defined operator can be either a user-defined dot operator or (an overload of) an intrinsic operator, as in the preceding examples. If it is an intrinsic operator it must not redefine an intrinsic operation - for example, the + operator must not be given an operator interface for a function with two integer arguments, as that would be an attempt to redefine addition of two integer values. All operator definitions are considered to be generic procedure definitions and must be consistent with the generic reference resolution rules (see below). The function(s) associated with a defined operator may be either external functions (in which case the interface contains the corresponding interface bodies, as in the above example) or accessible module functions (in which case the interface contains the corresponding *module-procedure* statements).

An example of a user-defined dot operator:

```
MODULE strings

INTERFACE OPERATOR (.CONCAT.)
    MODULE PROCEDURE concatenation
END INTERFACE
PRIVATE concatenation

CONTAINS
    FUNCTION concatenation(A, B)
        CHARACTER(LEN=*) , INTENT(IN) :: A, B
        CHARACTER(LEN=LEN_TRIM(A)+LEN_TRIM(B)) :: concatenation
        concatenation = TRIM(A)//TRIM(B)
    END FUNCTION concatenation
END MODULE strings
```

If a subroutine has two arguments, the first being intent(out) or intent(inout) and the second being intent(in), then it may be given an *assignment overload*:

```
interface assignment (=)
    [interface-body] ...
    [module-procedure-stmt] ...
end interface
```

An example is:

```
interface assignment (=)
```

```

subroutine to_char_from_int(c, i)
  character :: c
  integer :: i
end subroutine
end interface

```

The purpose of such a subroutine is to convert the value of the second argument to an appropriate value for the type of the first argument, and to assign this converted value to the first actual argument; the subroutine defines the conversion that takes place in such an assignment. The *assignment interface* makes it possible to use assignment syntax for this operation, as an alternative to using normal subroutine calls. In analogy with operator interfaces, assignment interfaces define assignment overloads and thus must be consistent with the generic reference resolution rules. Intrinsic assignments cannot be redefined except for intrinsic assignment of structures (that is, derived type intrinsic assignment). As with operator functions, assignment subroutines may be either external subroutines or module subroutines.

Interface blocks may be used to define overloaded (generic) procedure names. Any procedure name may be (further) overloaded, including an intrinsic procedure name:

```

interface generic-name
  [interface-body] ...
  [module-procedure-stmt] ...
end interface

```

A *generic name* may be associated with any number of external procedures and module procedures. Such a procedure may be called using either its original (specific) name or the generic name. A call to a procedure using the generic name is considered to be a generic reference; any generic reference must be resolvable to a specific procedure, in accordance with the generic reference resolution rules. Generally speaking, this means that each procedure sharing the same generic name must have a different argument “signature” (type pattern). External and module procedures may be given generic interfaces. For example:

```

INTERFACE LOGB
  MODULE PROCEDURE SP_LOGB, DP_LOGB
END INTERFACE LOGB

CONTAINS
  FUNCTION SP_LOGB(X)
    REAL(KIND(1.0E0)) :: SP_LOGB, X
    SP_LOGB = EXPONENT(X) - 1.0E0
  END FUNCTION SP_LOGB

  FUNCTION DP_LOGB(X)
    REAL(KIND(1.0D0)) :: DP_LOGB, X
    DP_LOGB = EXPONENT(X) - 1.0D0
  END FUNCTION DP_LOGB

```

A *module-procedure-stmt* takes the form of:

```

module procedure

```

Interface bodies are not necessary as the compiler will determine the interface from the actual implementation of the module procedure. An example would be:

```
interface c_associated
  module procedure c_associated_c_ptr, c_associated_c_funptr
end interface c_associated
```

CHAPTER 6

Expressions and Assignment Statements

Being primarily a computational language, a large number of FORTRAN statements employ expressions. The evaluation of an expression results in a single value which may be used to define a variable, take part in a logical decision, be written to a file, etc. The simplest form of an expression is a scalar value: a constant or single variable. More complicated expressions can be formed by specifying operations to be performed on one or more operands.

There are four types of expressions available in Fortran: arithmetic, character, relational, and logical. This chapter describes the rules for the formation and evaluation of these expressions.

Assignment statements, together with expressions, are the fundamental working tools of FORTRAN. Assignment statements are used to establish a value for variables and array elements. Assignment statements assign a value to a storage location.

ARITHMETIC EXPRESSIONS

An arithmetic expression produces a numeric result and is formed with integer, real, double precision, and complex operands and arithmetic operators. An arithmetic operand may be one of the following:

- an arithmetic scalar value
- an arithmetic array element
- an arithmetic expression enclosed in parentheses
- the result of an arithmetic function

The arithmetic operators are:

<u>Operator</u>	<u>Purpose</u>
**	exponentiation
*	multiplication
/	division
+	addition or identity
-	subtraction or negation

The operators **, *, and / operate only on pairs of operands, while + and - may operate on either pairs of operands or on single operands. Pairs of operators in succession are not

allowed: $A+B$ must be stated as $A+(-B)$. In addition, there is precedence among the arithmetic operators which establishes the order of evaluation:

<u>Operator</u>	<u>Precedence</u>
**	highest
* and /	intermediate
+ and -	lowest

Except for the exponentiation operator, when two or more operators of equal precedence occur consecutively within an arithmetic expression they may be evaluated in any order if the result of the expression is mathematically equivalent to the stated form. However, exponentiation is always evaluated from right to left:

<u>Expression</u>	<u>Evaluation</u>
$A+B-C$	$(A+B)-C$ or $A+(B-C)$
$A**B**C$	$A**(B**C)$
$A+B/C$	$A+(B/C)$

However, the result of an arithmetic expression involving integer operands and the division operator is the quotient; the remainder is discarded: $10/3$ produces an integer result of 3. Consequently, expressions such as $I*J/K$ may have different values depending on the order of evaluation:

$$(4*5)/2 = 10, \text{ but } 4*(5/2) = 8$$

Data Type of Arithmetic Expressions

When all of the operands of an arithmetic expression are of the same data type, the data type of the result is the same as that of the operands. When expressions involving operands of different types are evaluated, automatic conversions between types occur. These conversions are always performed in the direction of the highest ordered data type presented and the data type of the result is that of the highest ordered operand encountered. `INTEGER` is the lowest ordered data type and `COMPLEX` is the highest.

Data Type Conversion Order

`INTEGER`
`REAL`
`DOUBLE PRECISION`
`COMPLEX`
`COMPLEX*16`

Consider the expression $I/R*D+C$, where I is `INTEGER`, R is `REAL`, D is `DOUBLE PRECISION`, and C is `COMPLEX`. The evaluation proceeds as follows:

- the value of I is converted to `REAL` and then divided by the value of R

- the result of the division is implicitly converted to `DOUBLE PRECISION` and multiplied by the value of `D`
- the result of the multiplication is then added to the real portion of the of the value `C` giving `DOUBLE PRECISION`
- the imaginary portion of the value `C` is implicitly converted to `DOUBLE PRECISION` in the final result
- the data type of the result of the expression is `COMPLEX*16`

Parentheses are used to force a specific order of evaluation that the compiler may not override.

When exponentiation of `REAL`, `DOUBLE PRECISION`, and `COMPLEX` operands involves integer powers, the integer power is not converted to the data type of the other operand. Exponentiation by an integer power is a special operation which allows expressions such as `-2.1**3` to be evaluated correctly.

Conversion from a lower to a higher precision does not increase the accuracy of the converted value. For example, converting the result of the real expression `1.0/3.0` to `DOUBLE PRECISION` yields:

`0.333333343267441D+00`

not:

`0.333333300000000D+00` or `0.333333333333333D+00`

Arithmetic Constant Expression

Arithmetic expressions in which all of the operands are constants or the symbolic names of constants are called arithmetic constant expressions. `INTEGER`, `REAL`, `DOUBLE PRECISION`, and `COMPLEX` constant expressions may be used in `PARAMETER` statements. Integer constant expressions may also be used in specification and declaration statements (see the **Specifications and DATA Statements** chapter).

CHARACTER EXPRESSIONS

A `CHARACTER` expression produces a character result and is formed using character operands and character operators. A `CHARACTER` operand may be one of the following:

- a `CHARACTER` scalar value
- a `CHARACTER` array element
- a `CHARACTER` substring
- a `CHARACTER` expression enclosed in parentheses
- the result of a `CHARACTER` function

The only `CHARACTER` operator is `//`, meaning concatenation. Although parentheses are allowed in character expressions, they do not alter the value of the result. The following character expressions all produce the value `'CHARACTER'`:

```
'CHA'// 'RAC'// 'TER'  
( 'CHA'// 'RAC' )// 'TER'  
'CHA'// ( 'RAC'// 'TER' )
```

RELATIONAL EXPRESSIONS

A relational expression produces a logical result (`.TRUE.` or `.FALSE.`) and is formed using arithmetic expressions or `CHARACTER` expressions and relational operators. The relational operators perform comparisons; they are:

<u>Operator</u>	<u>Comparison</u>
<code><</code> or <code>.LT.</code>	less than
<code><=</code> or <code>.LE.</code>	less than or equal to
<code>==</code> or <code>.EQ.</code>	equal to
<code>/=</code> or <code>.NE.</code>	not equal to
<code><></code> or <code>.NE.</code>	not equal to
<code>></code> or <code>.GT.</code>	greater than
<code>>=</code> or <code>.GE.</code>	greater than or equal to

Only the `.EQ.` and `.NE.` relational operators can be applied to complex operands.

All of the relational operators have the same precedence which is lower than the arithmetic operators and the character operator.

If the data types of two arithmetic operands are different, the operand with the lowest order is converted to the type of the other operand before the relational comparison is performed. The same type coercion rules apply to relational operators as arithmetic operators when comparisons are made, but results are always returned as `LOGICAL`.

Character comparison proceeds on a character by character basis using the ASCII collating sequence to establish comparison relationships. Since the letter 'A' precedes the letter 'B' in the ASCII code, 'A' is less than 'B'. Also, all of the upper case characters have lower "values" than the lower case characters. A complete chart of the ASCII character set is provided in the appendices.

When the length of one of the `CHARACTER` operands used in a relational expression is shorter than the other operand, the comparison proceeds as though the shorter operand were extended with blank characters to the length of the longer operand.

When an integer value is compared with a `CHARACTER` constant, one to four bytes of the character string are extracted as an integer and a comparison is made between the two integer values. This is useful if the integer has been defined with a Hollerith data type. This type of comparison is only defined for character constants with a length less than or equal to four.

LOGICAL EXPRESSIONS

A `LOGICAL` expression is formed with `LOGICAL` or `INTEGER` operands and logical operators. A `LOGICAL` operand may be one of the following:

- a `LOGICAL` or `INTEGER` scalar value
- a `LOGICAL` or `INTEGER` array element
- a `LOGICAL` or `INTEGER` expression enclosed in parentheses
- a relational expression
- the result of a `LOGICAL` or `INTEGER` function

A `LOGICAL` expression involving `LOGICAL` operands and relational expressions produces a `LOGICAL` result (`.TRUE.` or `.FALSE.`). When applied to `LOGICAL` operands the logical operators, their meanings, and order of precedence are:

<u>Operator</u>	<u>Purpose</u>	<u>Precedence</u>
<code>.NOT.</code>	negation	highest
<code>.AND.</code>	conjunction	
<code>.OR.</code>	inclusive disjunction	
<code>.EQV.</code>	equivalence	lowest
<code>.NEQV.</code>	nonequivalence	
<code>.XOR.</code>	nonequivalence	same as <code>.NEQV.</code>

A LOGICAL expression involving INTEGER operands produces an INTEGER result. The operation is performed on a bit-wise basis. When applied to integer operands the logical operators have the following meanings:

<u>Operator</u>	<u>Purpose</u>
.NOT.	one's complement
.AND.	Boolean and
.OR.	Boolean or
.EQV.	integer compare
.NEQV.	Boolean exclusive or
.XOR.	Boolean exclusive or

Note that expressions involving INTEGER and LOGICAL operands are ambiguous.

Consider the following example:

```
LOGICAL l,m
INTEGER i

i = 2
l = .TRUE.
IF (l .AND. i) WRITE(*,*) "first if clause executed"
m = i
IF (l .AND. m) WRITE(*,*) "second if clause executed"
END
```

Since the LOGICAL constant .TRUE. has a value of one when converted to INTEGER, the first IF clause would not normally be executed since a Boolean .AND. between the values one and two produces a zero which is logically false. For this reason, integers are converted to LOGICAL when the .AND. operator is used with a LOGICAL. The second IF clause will execute since the conversion of a non-zero INTEGER to LOGICAL (in the assignment statement `m = i`) gives the value .TRUE. (stored as the value one). Note that the above code is not guaranteed to be portable to other FORTRAN environments.

OPERATOR PRECEDENCE

As described above, a precedence exists among the operators used with the various types of expressions. Because more than one type of operator may be used in an expression, a precedence also exists among the operators taken as a whole: arithmetic is the highest, followed by character, then relational, and finally logical which is the lowest.

```
A+B .GT. C .AND. D-E .LE. F
```

is evaluated as:

```
((A+B) .GT. C) .AND. ((D-E) .LE. F)
```

ARITHMETIC ASSIGNMENT STATEMENT

Arithmetic assignment statements are used to store a value in arithmetic variables. Arithmetic assignment statements take the following form:

$$v = e$$

where: v is the symbolic name of an integer, real, double precision, or complex variable or array element whose contents are to be replaced by e .

e is a character constant or arithmetic expression.

If the data type of e is arithmetic and different than the type of v , then the value of e is converted to the type of v before storage occurs. This may cause truncation.

If e is a CHARACTER constant, bytes of data will be moved directly to the storage location with no type conversion. If e is a CHARACTER expression, a type mismatch error will occur.

LOGICAL ASSIGNMENT STATEMENT

LOGICAL assignment statements are used to store a value in LOGICAL variables. LOGICAL assignment statements are formed exactly like arithmetic assignment statements:

$$v = e$$

where: v is the symbolic name of a logical variable or logical array element.

e is an arithmetic or logical expression.

If the data type of e is not LOGICAL, the value assigned to v is the LOGICAL value .FALSE. if the value of the expression e is zero. For non-zero values of e , the value assigned to v is the LOGICAL value .TRUE.. This rule for the conversion of an arithmetic expression to a LOGICAL value applies wherever a LOGICAL expression is expected (i.e. an IF statement).

CHARACTER ASSIGNMENT STATEMENT

CHARACTER assignment statements are used to store a value in CHARACTER variables:

$$v = e$$

where: v is the symbolic name of a character variable, character array element, or character substring. e is an expression whose type is character.

If the length of e is greater than the length of v , the leftmost characters of e are used.

If the length of e is less than the length of v , blank characters are added to the right of e until it is the same length as v .

ASSIGN STATEMENT

The ASSIGN statement is used to store the address of a labeled statement in an integer variable. Once defined with a statement label, the integer variable may be used as the destination of an assigned GOTO statement (**Control Statements** chapter) or as a format descriptor in an I/O statement (**Input/Output and Format Specification** chapter). The ASSIGN statement is given in the following manner.

$$\text{ASSIGN } s \text{ TO } i$$

where: s is the label of a statement appearing in the same program unit that the ASSIGN statement does.

i is an INTEGER variable name.

Caution: No protection is provided against attempting to use a variable that does not contain a valid address as established with the ASSIGN statement.

CHAPTER 7

Control Statements

Control statements direct the flow of execution in a Fortran program. Included in the control statements are constructs for looping, conditional and unconditional branching, making multiple choice decisions, and halting program execution.

GOTO STATEMENTS

Unconditional GOTO

The unconditional `GOTO` statement causes immediate transfer of control to a labeled statement:

```
GOTO s
```

The statement label `s` must be in the same program unit as the `GOTO` statement.

Computed GOTO

The computed `GOTO` statement provides a means for transferring control to one of several different destinations depending on a specific condition:

```
GOTO (s [,s]...) [,] e
```

`e` is an expression which is converted as necessary to integer and is used to select a destination from one of the statements in the list of labels (`s [,s]...`). The selection is made such that if the value of `e` is one, the first label is used, if the value of `e` is two, the second label is used, and so on. The same label may appear more than once in the label list. If the value of `e` is less than 1 or greater than the number of labels in the list no transfer is made. All of the statement labels in the list must be in the same program unit as the computed `GOTO` statement.

Assigned GOTO

The assigned `GOTO` statement is used with an integer variable that contains the address of a labeled statement as established with an `ASSIGN` statement:

```
GOTO i [[,] (s [,s]...)]
```

The address of the labeled statement contained in the integer variable `i` is used as the destination. If the optional list of statement labels, (`s [,s]...`), appears then `i` must be defined with the address of one of them or no transfer is made.

IF STATEMENTS**Arithmetic IF**

The arithmetic `IF` statement is used to transfer control based on the sign of the value of an expression:

```
IF (e) s1 , s2 , s3
```

e can be an `INTEGER`, `REAL`, or `DOUBLE PRECISION` expression which if negative, transfers control to the statement labeled *s1*; if zero, transfers control to the statement labeled *s2*; and if positive, transfers control to the statement labeled *s3*. The statements labeled *s1*, *s2*, and *s3* must be in the same program unit as the arithmetic `IF` statement.

Logical IF

The logical `IF` statement is used to execute another statement based on the value of a logical expression:

```
IF (e) st
```

The statement *st* is executed only if the value of the logical expression *e* is `.TRUE.`. The statement *st* cannot be any of the following: `DO`, `IF`, `ELSE IF`, `ELSE`, `END IF`, `END`, `END DO`, `REPEAT`, `SELECT CASE`, `CASE`, or `END SELECT`.

Block IF

A block `IF` consists of `IF (e) THEN`, `ELSE`, and `END IF` statements. Each `IF (e) THEN` statement must be balanced by an `END IF` statement. A block `IF` provides for the selective execution of a particular block of statements depending on the result of the `LOGICAL` expression *e*.

```
[if-construct-name:] IF (e) THEN  
    block of statements  
ELSE [if-construct-name]  
    block of statements  
END IF [if-construct-name]
```

The `ELSE` statement and the second block of statements are optional. If the value of the `LOGICAL` expression *e* is `.TRUE.`, the first block of statements is executed and then control of execution is transferred to the statement immediately following the `END IF` statement. If *e* has a `.FALSE.` value, then, if a second block of statements exists (constructed by `ELSE` or `ELSE IF` statements) it is executed, and control of execution is transferred to the statement immediately following the `END IF` statement.

A block `IF` construct may be labeled with an *if-construct-name* for clarity.

Each block of statements may contain more block IF constructs. Since each block IF must be terminated by an END IF statement there is no ambiguity in the execution path.

A more complicated block IF can be constructed using the alternate form of the ELSE statement: the ELSE IF (e) THEN statement. Multiple ELSE IF (e) THEN statements can appear within a block IF, each one being evaluated if the previous logical expression e has a .FALSE. value:

```
IF (I.GT.0 .AND. I.LE.10) THEN
    block of statements
ELSE IF (I.GT.10 .AND. I.LE.100) THEN
    block of statements
ELSE IF (I.GT.100 .AND. I.LE.1000) THEN
    block of statements
ELSE
    block of statements
END IF
```

LOOP STATEMENTS

The DO statements provide the fundamental structure for constructing loops in Fortran. The standard DO loop is discussed in this section.

Basic DO loop

The basic DO statement takes the following form:

```
DO [s [,]] i = e1, e2 [, e3]
```

where: *s* is the label of the statement that defines the range of the DO loop and must follow the DO statement in the same program unit. If *s* is omitted, the loop must be terminated with an END DO statement.

i is called the DO variable and must be either an INTEGER, REAL, or DOUBLE PRECISION scalar variable

e1, *e2*, and *e3* may be integer, real, or double precision expressions whose values are called the initial value, the limit value, and the increment value, respectively

The loop termination statement, labeled *s*, if present, must not be a DO, arithmetic IF, block IF, ELSE, END IF, unconditional GOTO, assigned GOTO, RETURN, STOP, END, SELECT CASE, CASE, or END SELECT statement.

DO loops may be nested to any level, but each nested loop must be entirely contained within the range of the outer loop. The termination statements of nested DO loops may be the same.

DO loops may appear within IF blocks and IF blocks may appear within DO loops, but each structure must be entirely contained within the enclosing structure.

DO Loop Execution

The following steps govern the execution of a DO loop:

1. The expression $e1$, the initial value, is evaluated and assigned to the DO variable i , with appropriate type conversion as necessary.
2. The expressions $e2$ and $e3$, the limit value and increment value respectively, are evaluated. If $e3$ is omitted, it is given the default value of one.
3. The iteration count is calculated from the following expression:

$$\text{MAX}(\text{INT}((e2 - e1 + e3)/e3), 0)$$

and determines how many times the statements within the loop will be executed.

4. The iteration count is tested, and if it is zero, control of execution is transferred to the statement immediately following the loop termination statement.
5. The statements within the range of the loop are executed.
6. The DO variable is increased by the increment value, the iteration count is decreased by one, and control branches to step four.

Variables that appear in the expressions $e1$, $e2$, and $e3$ may be modified within the loop, without affecting the number of times the loop is iterated.

```
      K = 0
      L = 10
      DO 10 I=1, L
      DO 10 J=1, I
      L = J
10    K = K+1
```

When the execution of both the inner and outer loops is finished, the values of both I and J are 11, the value of K is 55, and the value of L is 10.

DO WHILE

The `DO WHILE` statement provides a method of looping not necessarily governed by an iteration count. The form of the `DO WHILE` statement is:

```
DO WHILE (e)
```

where: *e* is a LOGICAL expression.

The `DO WHILE` statement tests the LOGICAL expression at the top of the loop. If the expression evaluates to a `.TRUE.` value, the statements within the body of the loop are executed. If the expression evaluates to a `.FALSE.` value, execution proceeds with the statement following the loop:

```
INTEGER          :: status
INTEGER, PARAMETER :: eof=1

DATA a,b,c /3*0.0/

status = 0
DO WHILE (status<>eof)
    c = c + a*b
    READ (*,*,IOSTAT=status) a,b
END DO
```

Infinite DO

```
DO
    block
END DO
```

This is essentially a `DO` forever construct for use in situations where the number of loop iterations is unknown and must be determined from some external condition (i.e. processing text files).

END DO statement

The `END DO` statement is used to terminate `DO` loops. After execution of an `END DO` statement, the next statement executed depends on the result of the `DO` loop incrementation processing. The form of the `END DO` statement is:

```
END DO
```

EXIT statement

The `EXIT` statement provides a convenient means for abnormal termination of a `DO` loop. This statement cause control of execution to be transferred to the statement following the terminal statement of a `DO` loop or block `DO`.

```
DO
    READ (*,*,IOSTAT=ios) v1,v2; IF (ios==-1) EXIT
    CALL process(v1,v2)
END DO
```

CYCLE statement

The `CYCLE` statement causes immediate loop index and iteration count processing to be performed for the `DO` loop or block `DO` structure to which the `CYCLE` statement belongs.

```
READ (*,*) n
z = 0.0
DO (n TIMES)
    READ (*,*) x,y; IF (y==0.0) CYCLE
    z = z + x/y
END DO
```

CONTINUE STATEMENT

The `CONTINUE` statement is used to provide a reference point. It is usually used as the terminating statement of a basic `DO` loop, but it can appear anywhere in the executable section of a program unit. Executing the `CONTINUE` statement itself has no effect. The form of the `CONTINUE` statement is:

```
CONTINUE
```

Labeled DO loops

`DO` loops may use labels for clarity and allow iterating or exiting a specific loop. The label is called a *do-construct-name*. If a `DO` loop is labeled with a *do-construct-name*, the corresponding `END DO` statement must have the same *do-construct-name*. `CYCLE` and `EXIT` statements may mention a *do-construct-name* to indicate the specific loop they refer to. Examples:

```
outer_loop: do
    . . .
inner_loop:  do
    . . .
            if ( . . . ) cycle inner_loop
            if ( . . . ) exit outer_loop
    . . .
end do inner_loop
    . . .
end do outer_loop
```

BLOCK CASE

The block `CASE` structure is an extension to the FORTRAN standard for constructing blocks which are executed based on comparison and range selection. The `SELECT CASE` statement is used with an `END SELECT` statement, at least one `CASE` statement and, optionally, a `CASE DEFAULT` statement to control the execution sequence. The `SELECT CASE` statement is used to form a block `CASE`.

The form of a block `CASE` is:

```
[case-construct-name] SELECT CASE (e)
    CASE (case_selector) [case-construct-name]
        [block]
    [CASE (case_selector) [case-construct-name]
        [block]
    ...]
    [CASE DEFAULT [case-construct-name]
        [block]
END SELECT [case-construct-name]
```

where: *e* is an expression formed from one of the enumerative data types: `CHARACTER`, `INTEGER`, `REAL`, or `DOUBLE PRECISION`. For the purposes of the block `CASE` construct, the value of `CHARACTER` expression is its position in the ASCII collating sequence.

case-construct-name is an optional label than may be used for identification. If a *case-construct-name* is used is must be the same for each element of the `CASE` structure.

A `CASE` block must contain at least one `CASE` statement and must be terminated by an `END SELECT` statement. Control of execution must not be transferred into a block `CASE`.

`CASE` blocks are delimited by a `CASE` statement and the next `CASE`, `CASE DEFAULT`, or `END SELECT` statement. A `CASE` block may be empty. After execution of a `CASE` block, control of execution is transferred to the statement following the `END SELECT` statement with the same `CASE` level. Block `CASE` structures may be nested. Since each block `CASE` must be terminated by an `END SELECT` statement there is no ambiguity in the execution sequence.

A *case_selector* takes the form of either of the following:

```
CASE (con[, con, ..., con])
```

```
CASE DEFAULT
```

con may be either a value selector or a range selector. A value selector is a constant. A range selector takes one of the following three forms:

```
con1:con2            where    (con1 .LE. e) .AND. (e .LE. con2)
```

```
con:                where    con .LE. e
```

```
:con                where    e .LE. con
```

All constants must be of the same type as the expression *e* in the `SELECT CASE` statement. A block `CASE` may have only one `CASE DEFAULT` statement where control of execution is transferred if no match is found in any other `CASE` statement. If a `CASE DEFAULT` statement is not present and no match is found, a run-time error is reported.

Execution of a block CASE statement

Execution of block `CASE` statement causes evaluation of the expression *e* in the `SELECT CASE` statement. The value of the expression is then compared sequentially with the parameters of the case selectors. If a match is made, transfer of control is passed to that case block. If the comparison fails, the next case selector is checked.

Block CASE Example

```

*
*   routine to count the number and types of characters
*   in a text file
*
IMPLICIT INTEGER(a-z)
CHARACTER line*80
PARAMETER (eof=-1)

lines=0; alf=0; num=0; blk=0; trm=0; spl=0

DO
  READ (*,'(a)',IOSTAT=ios) line
  IF (ios==eof) EXIT
  chars = LEN(TRIM(line))
  lines = lines+1
  DO (i=1, chars)
    SELECT CASE (line(i:i))
      CASE ("A":"Z","a":"z")
        alf = alf+1
      CASE ("0":"9")
        num = num+1
      CASE (" ")
        blk = blk+1
      CASE (".", "!", "?")
        trm = trm+1
      CASE DEFAULT
        spl = spl+1
    END SELECT
  END DO
END DO

END

```

STOP STATEMENT

The `STOP` statement terminates execution of a program:

```
STOP [s]
```

The optional string *s* may be a `CHARACTER` constant or string of five or fewer digits and is output to standard out with end of record characters.

PAUSE STATEMENT

The `PAUSE` statement suspends execution until a carriage return character is read from standard input (usually from the keyboard).

```
PAUSE [s]
```

The optional string *s* may be a CHARACTER constant or string of five or fewer digits and is output to unit * without end of record characters.

END STATEMENT

Every program unit must have an END statement which terminates the range of individual program units within a source file. A source file itself may contain more than one program unit; the entry points of the individual program units in the compiled object file are available to the linker.

An END statement is executable and if encountered in a main program has the effect of a STOP statement and if encountered in a subroutine or function subprogram has the effect of a RETURN statement. An END statement is given on a statement line by itself with no other characters:

```
END
```

WHERE

The WHERE keyword can be used both as a statement and a construct, similar to the IF keyword. WHERE is used to perform masked array assignments, applying a logical test to each element of an array. The syntax of the WHERE statement is:

```
WHERE ( mask_expr ) assign_stmt
```

where: *mask_expr* is a logical array expression

assign_stmt is an array assignment statement. The shape of the array must be the same as the shape of the array used in the *mask_expr*

In the following example, the arcsine function will only be evaluated if the absolute value of the element of the array *a* is less than or equal to 1.0.

```
REAL a(100), b(100)
.
.
.
WHERE (ABS(a) <= 1.0) b = ASIN(a)
```

The syntax of the WHERE construct is:

```
[name:] WHERE ( mask_expr )
    [where_body_construct]
[ELSEWHERE ( mask_expr ) [name]
    where_body_construct]
[ELSEWHERE [name]
    where_body_construct]
END WHERE [name]
```

where: *mask_expr* is a logical array expression

where_body_construct is an array assignment statement or a WHERE statement or construct. The shape of all arrays must be the same as the shape of the array used in the *mask_expr*

Example:

```
REAL, DIMENSION(10,10) :: A

WHERE (A <= 10.0)
  A = A - 0.5
ELSEWHERE (A <= 100.0)
  A = A - 5.0
ELSEWHERE
  A = A - 50.0
END WHERE
```

FORALL

The FORALL keyword can be used both as a statement and a structure. It is similar to the masked array assignment WHERE, but is more general, allowing more array shapes to be assigned. It is used to perform array assignments, possibly masked, on an element by element basis. The syntax of the FORALL statement is:

```
FORALL (triplet_spec [, triplet_spec]... [, mask_expr] ) assign_stmt
```

where: *triplet_spec* is a triplet specification of an index variable normally used as an array element index. It has the following form:

```
index = subscript : subscript [: stride]
```

where: *index* is a scalar integer variable. It is valid only with the scope of the FORALL statement

subscript is a scalar integer expression and may not contain a reference to any *index* in the *triplet_spec* in which it appears

stride is a scalar integer expression and may not be zero. If omitted, a default value of 1 is supplied. It may not contain a reference to any *index* in the *triplet_spec* in which it appears

mask_expr is any logical scalar expression, including one which references an *index* of a *triplet_spec*.

assign_stmt is an assignment statement or a pointer assignment statement.

In the following example, every element of the array `a` is assigned the value 1.0.

```
REAL a(100, 100)
.
.
.
FORALL (i=1:100, j=1,100) a(i,j) = 1.0
```

The syntax of the `FORALL` construct is:

```
[name:] FORALL (triplet_spec [,triplet_spec]... [,mask_expr] )assign_stmt
      forall_body_construct
END FORALL [name]
```

where: *triplet_spec* is a triplet specification of an index variable normally used as an array element index. It has the following form:

index = *subscript* : *subscript* [: *stride*]

where: *index* is a scalar integer variable. It is valid only with the scope of the `FORALL` statement

subscript is a scalar integer expression and may not contain a reference to any *index* in the *triplet_spec* in which it appears

stride is a scalar integer expression and may not be zero. If omitted, a default value of 1 is supplied. It may not contain a reference to any *index* in the *triplet_spec* in which it appears

mask_expr is any logical scalar expression, including one which references an *index* of a *triplet_spec*.

forall_body_construct is an assignment statement, pointer assignment statement, `WHERE` statement or construct, or `FORALL` statement or construct.

CHAPTER 8

Input/Output and FORMAT Specification

Input and output statements provide a channel through which Fortran programs can communicate with the outside world. Facilities are available for accessing disk and tape files, communicating with terminals and printers, and controlling external devices. Fortran input and output statements are designed to allow access to the wide variety of features implemented on various computer systems in the most portable manner possible.

A format specification is used with formatted input and output statements to control the appearance of data on output and provide information regarding the type and size of data on input. Converting the internal binary representation of a floating point number into a string of digits requires a format specification and is called editing. A format specification divides a record into fields, each field representing a value. An explicitly stated format specification designates the exact size and appearance of values within fields.

When an asterisk (*) is used as a format specification it means “list directed” editing. Instead of performing editing based on explicitly stated formatting information, data will be transferred in a manner which is “reasonable” for its type and size.

Throughout the remainder of this chapter, input and output will be referred to in the conventional abbreviated form: I/O.

RECORDS

All FORTRAN I/O takes place through a data structure called a record. A record can be a single character or sequence of characters or values. A record might be a line of text, the data received from a bar code reader, the coordinates to move a plotter pen, or a punched card. FORTRAN uses three types of records:

- Formatted
- Unformatted
- Endfile

Formatted Record

A formatted record is a sequence of ASCII characters. It may or may not be terminated depending on the operating system. If it is terminated, the usual terminating characters are a carriage return, a line feed, or both. A single line of text on this page is a formatted record. The minimum length of a formatted record is zero. The maximum record length is limited only by available memory.

Unformatted Record

An unformatted record is a sequence of values. Its interpretation is dependent on the data type of the value. For example, the binary pattern 01010111 can be interpreted as the integer value 87 or the character value “W” depending on its data type. The minimum length of an unformatted record is zero. Records in unformatted sequential access files which contain no record length information (see below) have unlimited length. Records in unformatted sequential access files that contain imbedded record length information have a maximum size of 2,147,483,647 bytes. The maximum length of direct access unformatted records is limited only by available memory.

Endfile Record

The endfile record is the last record of a file and has no length. An endfile record may or may not be an actual record depending on the file system of a particular operating system.

FILES

A file is composed of zero or more records and can be created and accessed by means other than Fortran programs. For example, a text processor might be used to create and edit a document file and a Fortran program used to manipulate the information in the file.

Files that are usually stored on disks or tapes are called external files. Files can also be maintained in main memory. These are called internal files.

File Name

Most external files are accessed explicitly by their names. While the file naming conventions of operating systems vary greatly, Fortran can accommodate most of the differences. The circumstances where a name is not required to access a file are discussed later in this chapter.

File Position

The position within a file refers to the next record that will be read or written. When a file is opened it is usually positioned to just before the first record. The end of the file is just after the last record. Some of the I/O statements allow the current position within a file to be changed.

File Access

The method used to transfer records to and from files is called the access mode. External files may contain either formatted or unformatted records. When the records in a file can be read or written in an arbitrary manner, randomly, the access mode is direct. Individual records are accessed through a record number, a positive integer. All of the records in a direct access file have the same length and contain only the data actually written to them;

there are no record termination characters. Records may be rewritten, but not deleted. Generally, only disk files can use the direct access mode of record transfer.

When the records are transferred in order, one after another, the access mode is sequential. The records in a sequential access file may be of different lengths. Some files, like terminals, printers, and tape drives, can only use the sequential access mode.

Formatted sequential access files usually contain textual information and each record has a terminating character(s) as described above.

Unformatted sequential access is generally used for two conflicting, but equally common purposes:

- For controlling external devices such as plotters, graphics terminals, and machinery as well as processing unencoded binary information such as object files. In this case it is important that the data transferred to and from the external media be a true byte stream containing no record length information.
- For its data compression and speed of access characteristics. In this case it must be possible to determine the length of a record for partial record reads and backspacing purposes.

This implementation of Fortran contains provisions for both of these requirements. The default manner of unformatted processing of a sequential access is to imbed record length information for a maximum record size of 2,147,483,647 bytes. The `OPEN` statement `FORM` and `ACCESS` specifiers provide mechanisms for disabling record length information (see below).

Internal Files

Internal files are comprised of `CHARACTER` variables, `CHARACTER` array elements, `CHARACTER` substrings, or `CHARACTER` arrays. An internal file which is a `CHARACTER` variable, `CHARACTER` array element, or character substring has one record whose length is the length of the character entity. An internal file that is a `CHARACTER` array has as many records as there are array elements. The length of an individual record is the length of a `CHARACTER` array element. Data may only be transferred through the formatted sequential access mode. Internal files are usually used to convert variables between numeric and `CHARACTER` data types.

Input/Output Editing

Editing provides the means for converting between the internal format of a value and the external format:

internal	01000100010000110100001001000001
----------	----------------------------------

<u>external</u>	<u>interpretation</u>
ABCD	character
1145258561	integer
781.035	floating point

See **Giving A Format Specification** later in this chapter

I/O SPECIFIERS

Fortran I/O statements are formed with lists of specifiers that are used to identify the parameters of the operation and direct the control of execution when exceptions occur.

Unit Specifier

The mechanism through which a channel of communication with a file is established and maintained is called a unit. A unit may be either explicitly or implicitly identified, and may refer to an external or internal file. When the channel is established, the unit is said to be connected to the file. The relationship is symmetric; that is, you can also say that the file is connected to the unit.

A connection to an external file is established and maintained with an external unit identifier that is an integer expression whose value is an arbitrary positive integer. An external unit identifier is global to the program; a file opened in one program unit may be referenced with the same unit number in other program units. There is no relationship between a FORTRAN unit specifier and the numbers used by various operating systems to identify files.

A connection to an internal file is made with an internal file identifier which is the name of the CHARACTER variable, CHARACTER array element, CHARACTER substring, or CHARACTER array that comprises the file.

Unit numbers that are “preconnected” to system devices and default files are:

1. Unit 0 is preconnected to “standard error”, usually the screen.
2. Unit 5 is preconnected to “standard input”, usually the keyboard, for input operations; unit 5 is preconnected to “standard output”, usually the screen, for output operations; and unit 9 is preconnected to both “standard input” and “standard output”.
3. An asterisk as a unit identifier refers to “standard input” for input operations and “standard output” for output operations.
4. All other unit numbers are preconnected to default files for sequential input and output operations. If a sequential input or output operation references a unit which has not been connected with a FORTRAN OPEN statement, the effect is as if an OPEN statement with only the

`UNIT=` specifier present had been executed to connect the unit. Execution of direct access input and output operations is not permitted on preconnected units.

With the exception of the asterisk, the preconnection of a unit number may be defeated by explicitly connecting the unit number to a file with the FORTRAN `OPEN` statement.

A unit specifier is given as:

`[UNIT=] u`

where: `u` is either a positive `INTEGER` expression representing an external unit identifier, or a `CHARACTER` entity representing an internal file identifier.

The characters `UNIT=` may be omitted if the unit identifier occurs first in the list of identifiers.

Implicit File Connections

If an input/output statement specifies a unit that was not connected to a file with an `OPEN` statement, a file is implicitly connected to the unit. The file is given the name:

`fort.n`

where `n` is the unit number used in the connection.

Format Specifier

The format specifier establishes the method of converting between internal and external representations. It can be given in one of two ways:

`[FMT=] f`

or

`[FMT=] *`

where: `f` is the statement label of a `FORMAT` statement, an integer variable that has been assigned a `FORMAT` statement label with an `ASSIGN` statement, a `CHARACTER` array name, or any `CHARACTER` expression

* indicates “list directed” editing

The characters `FMT=` may be omitted if the format specifier occurs second in the list of identifiers and the first item is the unit specifier with the characters `UNIT=` also omitted. The following are equivalent:

```
WRITE (UNIT=9, FMT=1000)
WRITE (9,1000)
```

Namelist Specifier

The namelist specifier establishes that conversion from internal and external representations is to be accomplished through namelist directed I/O and is given as:

$$[NML=] \ n$$

where n is the name of a previously defined namelist identifier.

The characters `NML=` may be omitted if the namelist specifier occurs second in the list of identifiers and the first item is the unit specifier with the characters `UNIT=` also omitted.

Record Specifier

The record specifier establishes which direct access record is to be accessed and is given as:

$$REC = \ rn$$

where rn is a positive integer expression.

Error Specifier

The error specifier provides a method to transfer control of execution to a different section of the program unit if an error condition occurs during an I/O statement. It takes as an argument the label of the statement where control is to be transferred:

$$ERR = \ s$$

where: s is the statement label.

End of File Specifier

The end of file specifier provides a method to transfer control of execution to a different section of the program unit if an end of file condition occurs during an I/O statement. It also takes as an argument the label of the statement where control is to be transferred:

$$END = \ s$$

where: s is the statement label.

To generate an end of file from the keyboard, type either Command-Return or Command-Enter.

I/O Status Specifier

The I/O status specifier is used to monitor error and end of file conditions after the completion of an I/O statement. Its associated integer variable becomes defined with a -1 if end of file has occurred, a positive integer if an error occurred, and zero if there is neither an error nor end of file condition:

`IOSTAT = ios`

where: `ios` is the symbolic name of an `INTEGER` variable or array element.

Partial Record Specifier

Fortran I/O is fundamentally record oriented, and explicit specification is needed for a read (write) statement to consume (produce) only part of a record. In (the default) whole-record I/O, the position of the file is said to *advance* to the next record after a read or a write statement. Thus partial-record I/O is called *nonadvancing* I/O, as the file position is “left where it is” rather than advancing to the beginning of the next record. In nonadvancing input the position of the file is left at the beginning of the next datum within the record that has not yet been read, and the next read statement continues reading from that point; in nonadvancing output an end-of-record is not written by the write statement, and the next write statement continues the same output record.

Nonadvancing I/O is specified with the `ADVANCE="NO"` in the read or write statement; nonadvancing can be specified only for sequential, formatted I/O:

`ADVANCE = as`

where: `as` is a `CHARACTER` expression that evaluates to `YES` or `NO`. The default is `YES`.

I/O LIST

The I/O list, `iolist`, contains the names of variables, arrays, array elements, and expressions (only in output statements) whose values are to be transferred with an I/O statement. The following items may appear in an `iolist`:

- A variable name
- An array element name
- A `CHARACTER` substring name
- An array name which is interpreted as every element in the array
- Any expression (only in an output statement)

Implied DO List In An I/O List

The elements of an iolist in an implied DO list are transferred as though the I/O statement was within a DO loop. An implied DO list is stated in the following manner:

(dlist, i = e1, e2 [,e3])

where: *i* is the DO variable

e1, *e2*, and *e3* establish the initial value, the limit value, and increment value respectively (see the **Control Statements** chapter).

dlist is an iolist and may consist of other implied DO lists

In a READ statement (see below), the DO variable, *i*, must not occur within *dlist* except as an element of subscript, but may occur in the iolist prior to the implied DO list.

DATA TRANSFER STATEMENTS

Data transfer statements transfer one or more records of data.

READ, WRITE AND PRINT

The READ statements transfer input data from files into storage and the WRITE and PRINT statements transfer output data from storage to files.

READ (*cilist*) [*iolist*]

READ *f* [,*iolist*]

WRITE (*cilist*) [*iolist*]

PRINT *f* [,*iolist*]

PRINT *n*

where: *f* is a format identifier

iolist is an I/O list

n is a list name previously defined in a NAMELIST statement

cilist is a parameter control list that may contain:

1. A unit specifier identifying the file connection.
2. An optional format specifier for formatted data transfers or an optional namelist specifier for namelist directed data transfers, but not both.

3. An optional record specifier for direct access connections.
4. An optional error specifier directing the execution path in the event of error occurring during the data transfer operation.
5. An optional end of file specifier directing the execution path in the event of end of file occurring during the data transfer operation.
6. An optional I/O status specifier to monitor the error or end of file status.

The `PRINT` statements, as well as the `READ` statements which do not contain a *cilist*, implicitly use the asterisk as a unit identifier.

ACCEPT AND TYPE

The `ACCEPT` statements transfer input data from records accessed in sequential mode and the `TYPE` statements transfer output data to records accessed in sequential mode.

```
ACCEPT f [, iolist]
```

```
ACCEPT n
```

```
TYPE f [, iolist]
```

```
TYPE n
```

where: *f* is a format identifier

iolist is an I/O list

n is a list name previously defined in a `NAMelist` statement

The `ACCEPT` and `TYPE` statements implicitly use the asterisk as a unit identifier.

Unformatted Data Transfer

Unformatted data transfer is permitted only to external files. One unedited record is transferred per data transfer statement.

Formatted Data Transfer

Formatted data transfer requires a format specifier which directs the interpretation applied to items in the *iolist*. Formatted data transfer causes one or more records to be transferred.

Printing

WRITE statements which specify a unit connected with ACTION='PRINT' in the OPEN statement (see below) use the first character of each record to control vertical spacing.

This character, called the carriage control character, is not printed and causes the following vertical spacing to be performed before the record is output:

<u>Character</u>	<u>Vertical Spacing</u>
blank	one line
0	two lines
1	top of page
+	no advance (over print)

Any other character appearing in the first position of record or a record containing no characters causes vertical spacing of one line.

OPEN STATEMENT

The OPEN statement connects a unit to an existing file, creates a file and connects a unit to it or modifies an existing connection. The OPEN statement has the following form:

```
OPEN ([UNIT=] u [, olist])
```

where: *u* is the external unit specifier

olist is optional and consists of zero or more of the following specifiers, each of which must have a variable or constant following the equal sign:

- | | | |
|--------|---|---|
| FILE | = | a CHARACTER expression which represents the name of the file to be connected to the unit. If this specifier is omitted and the specified unit is not currently connected, a file name will be created. |
| ACCESS | = | a CHARACTER expression which must be SEQUENTIAL, DIRECT, APPEND, or TRANSPARENT and specifies the access mode or position. The default value is SEQUENTIAL. TRANSPARENT disables the embedding of record length information. |
| ACTION | = | a CHARACTER expression which must be READ, WRITE, READWRITE, or PRINT. If READ is specified, only READ statements and file positioning statements are allowed to refer to the connection. If WRITE is specified, only WRITE, PRINT, and file positioning statements are allowed to refer to the connection. If BOTH is specified, any input/output statement may be used to refer to the connection. If PRINT is specified, the first character in each record is interpreted for carriage control (see the previous section on printing) and only WRITE and PRINT statements are |

	allowed to refer to the connection. The default for ACTION is BOTH.
BLANK	= a CHARACTER expression which must be NULL or ZERO specifying how blank characters in formatted numeric input fields are to be handled. A value of ZERO causes blanks in the input field (leading, embedded, and trailing) to be replaced with zeros. The default value is NULL and causes blanks to be ignored.
DELIM	= a CHARACTER expression which must be APOSTROPHE, QUOTE, or NONE and specifies delimiter for writing list-directed CHARACTER data.
ERR	= an error specifier as described above.
FORM	= a CHARACTER expression which must be FORMATTED, UNFORMATTED, or BINARY specifying the type of records in the file. The default value is UNFORMATTED for direct access files and FORMATTED for sequential access files. BINARY is UNFORMATTED without record length information.
IOSTAT	= an I/O status specifier as described above.
PAD	= a CHARACTER expression which must be YES or NO specifying whether blank padding is used for input. The default is NO.
POSITION	= a CHARACTER expression which must be REWIND, APPEND, or ASIS. If REWIND is specified the file is opened at its beginning position for input or output. If APPEND is specified, the file is opened at its end position for output. The default is ASIS and has the same effect as REWIND.
RECL	= a positive INTEGER expression which must be given for direct access file connections and specifies, in bytes, the length of each direct access record.
STATUS	= a CHARACTER expression which must be OLD, NEW, SCRATCH, REPLACE, or UNKNOWN. The file must already exist when OLD is specified. The file must <i>not</i> exist when NEW is specified. If SCRATCH is specified a file will be created which will exist only during the execution of the program and FILE= must not be specified. If UNKNOWN is specified, a file will be created if one does not already exist. The default value is UNKNOWN.
READONLY	a specifier without an equal sign equivalent to ACTION=READ.

CARRIAGECONTROL= a CHARACTER expression which must be `FORTRAN`, `LIST` or `NONE`. Setting the value to `FORTRAN` is equivalent to `ACTION='PRINT'`. Setting the value to `LIST` or `NONE` has no effect and is only supported for compatibility.

CONVERT = a CHARACTER expression which must evaluate to `BIG_ENDIAN` or `LITTLE_ENDIAN`. This specifier controls the byte ordering of binary data in unformatted files. The default is the ordering appropriate for the type of processor the compiler is installed on.

If a unit is already connected to a file, execution of an `OPEN` statement for that unit is allowed. If the file to be connected is not the same as the file which is connected, the current connection is terminated before the new connection is established. If the file to be connected is the same as the file which is connected, only the `BLANK=` and `ACTION=` specifiers may have a different value from the ones currently in effect. Execution of the `OPEN` statement causes the new values of `BLANK=` and `ACTION=` to be in effect.

CLOSE STATEMENT

The `CLOSE` statement flushes a file's buffers and disconnects a file from a unit. The `CLOSE` statement has the following form:

```
CLOSE ([UNIT=] u [, clist])
```

where: *u* is the external unit specifier.

clist is optional and consists of zero or more of the following specifiers, each of which must have a variable or constant following the equals sign:

IOSTAT = an I/O status specifier as described above.

ERR = an error specifier as described above.

STATUS = a character expression which must be `KEEP` or `DELETE` which determines whether a file will continue to exist after it has been closed. `STATUS` has no effect if the value of the `STATUS` specifier in the `OPEN` statement was `SCRATCH`. The default value is `KEEP`.

Normal termination of execution of a Fortran program causes all units that are connected to be closed.

BACKSPACE STATEMENT

The BACKSPACE statement causes the file pointer to be positioned to a point just before the previous record. The forms of the BACKSPACE statement are:

```
BACKSPACE u  
BACKSPACE ([UNIT=] u [, alist])
```

where: *u* is the external unit specifier.

alist is optional and consists of zero or more of the following specifiers:

IOSTAT = an I/O status specifier as described above.

ERR = an error specifier as described above.

REWIND STATEMENT

The REWIND statement causes the file pointer to be positioned to a point just before the first record. The forms of the REWIND statement are:

```
REWIND u  
REWIND ([UNIT=] u [, alist])
```

where: *u* is the external unit specifier.

alist is optional and consists of zero or more of the following specifiers:

IOSTAT = an I/O status specifier as described above.

ERR = an error specifier as described above.

ENDFILE STATEMENT

The ENDFILE statement does nothing to disk files. The forms of the ENDFILE statement are:

```
ENDFILE u  
ENDFILE ([UNIT=] u [, alist])
```

where: *u* is the external unit specifier.

alist is optional and consists of zero or more of the following specifiers:

IOSTAT = an I/O status specifier as described above.

ERR = an error specifier as described above.

FLUSH STATEMENT

The FLUSH statement causes any pending internal buffers associated with a data transfer statements to be completed. The forms of the FLUSH statement are:

```
FLUSH u
FLUSH ([UNIT=] u [, alist])
```

where: *u* is the external unit specifier.

alist is optional and consists of zero or more of the following specifiers:

IOSTAT = an I/O status specifier as described above.

ERR = an error specifier as described above.

INQUIRE STATEMENT

The INQUIRE statement is used to obtain information regarding the properties of files and units. The forms of the INQUIRE statement are:

```
INQUIRE ([UNIT=] u, ilist)
INQUIRE (FILE= fin, ilist)
INQUIRE (IOLENGTH= n) olist
```

The first form, inquiry by unit, takes a unit number as the principal argument and is used for making inquiries about specific units. The unit number, *u*, is a positive integer expression. The second form, inquiry by file, takes a file name as the principal argument and is used for making inquiries about specific named files. The file name, *fin*, is a character expression. The third form is used to determine the length in bytes of *olist*. *olist* is a list of variable names. Only one of UNIT=, FILE=, or IOLENGTH= may be specified. One or more of the following *ilist* specifiers are also used with the INQUIRE statement:

NUMBER = an INTEGER variable or array element which is defined with the number of the unit that is connected to the file.

NAMED = a LOGICAL variable or array element which is defined with a true value if the file has a name.

NAME = a CHARACTER variable or array element which is defined with the name of the file.

EXIST	=	a LOGICAL variable or array element which is defined with a true value if the unit or file exists.
OPENED	=	a LOGICAL variable or array element which is defined with a true value if the unit or file is connected.
ACCESS	=	a CHARACTER variable or array element which is defined with either the value SEQUENTIAL or DIRECT depending on the access mode.
SEQUENTIAL	=	a CHARACTER variable or array element which is defined with the value YES or NO indicating whether the file can be connected for sequential access.
DIRECT	=	a CHARACTER variable or array element which is defined with the value YES or NO indicating whether the file can be connected for direct access.
ACTION	=	a CHARACTER variable or array element which is defined with either the value READ, WRITE, or READWRITE depending on the action mode.
READ	=	a CHARACTER variable or array element which is defined with the value YES, NO, or UNKNOWN indicating whether the file can be read from.
WRITE	=	a CHARACTER variable or array element which is defined with the value YES, NO, or UNKNOWN indicating whether the file can be written to.
READWRITE	=	a CHARACTER variable or array element which is defined with the value YES, NO, or UNKNOWN indicating whether the file can be read from <i>and</i> written to.
FORM	=	a CHARACTER variable or array element which is defined with either the value FORMATTED or UNFORMATTED depending on whether the file is connected for formatted or unformatted I/O.
FORMATTED	=	a CHARACTER variable or array element which is defined with the value YES or NO indicating whether the file can be connected for formatted I/O.
UNFORMATTED	=	a CHARACTER variable or array element which is defined with the value YES or NO indicating whether the file can be connected for unformatted I/O.

BLANK	=	a CHARACTER variable or array element which is defined with either the value NULL or ZERO depending on how blanks are handled.
DELIM	=	a CHARACTER variable or array element which is defined with the value APOSTROPHE, QUOTE, or NONE.
ERR	=	an error specifier as described above.
IOSTAT	=	an I/O status specifier as described above.
PAD	=	a CHARACTER variable or array element which is defined with the value YES or NO.
POSITION	=	a CHARACTER variable or array element which is defined with the value ASIS, REWIND or APPEND.
RECL	=	an INTEGER variable or array element which is defined with the record length if the file is connected for direct access.
NEXTREC	=	an INTEGER variable or array element which is defined with the value of the next record number to be read or written.
IOLENGTH	=	RECL= value for an output item list.
SIZE	=	an INTEGER variable or array element which is defined with the size of the file in bytes.

Some of the specifiers may not be defined if a unit is not connected or a file does not exist. For example:

```
CHARACTER*20 FN,AM  
LOGICAL OS  
INTEGER RL  
INQUIRE (UNIT=18, OPENED=OS, NAME=FN, ACCESS=AM, RECL=RL)
```

If unit 18 is not connected to a file, OS will be defined with a false value, but FN, AM, and RL will be undefined. If unit 18 is connected for sequential access, OS, FN, and AM will be defined appropriately, but record length is meaningless in this context, and RL will be undefined.

ENCODE AND DECODE STATEMENTS

The `ENCODE` and `DECODE` statements use internal files to effectively transfer data in internal form to character form, and vice versa. `ENCODE` can be thought of as writing the *list* of variables to the `CHARACTER` variable *char_form* with space padding if necessary, while `DECODE` reads the values of the variables from *char_form*. The forms of the `ENCODE` and `DECODE` statements are:

```
ENCODE (count,fmt,char_form[,IOSTAT=ios][,ERR=label]) [list]
DECODE (count,fmt,char_form[,IOSTAT=ios][,ERR=label]) [list]
```

where: *count* is the number of characters to convert to character form in the `ENCODE` statement. It is the number of characters to convert to internal form in the `DECODE` statement.

fmt is a format specifier described in the **Format Specifier** section near the beginning of this chapter.

char_form is a scalar variable or array which will hold the converted character form for the `ENCODE` statement. It holds the character form to be converted for the `DECODE` statement.

ios is an `INTEGER*4` variable used to monitor error and end of file conditions. It is described in the **I/O Status Specifier** section near the beginning of this chapter.

label is a statement label at which execution will be continued in the event of an error during an `ENCODE` or `DECODE` conversion.

list is a list of variables separated by commas. These are in internal form.

The following example assigns the ASCII representation of the variables `I` and `J` to the character variable `C`. After the `ENCODE` statement, `C` equals " 123 456 ".

```
CHARACTER*20 C
I = 123
J = 456
ENCODE (20,100,C) I,J
100 FORMAT (2I4)
END
```

GIVING A FORMAT SPECIFICATION

An explicit format specification may be given in either a `FORMAT` statement or in a character array or character expression. A `FORMAT` statement must be labeled so that it can be referenced by the data transfer statements (`READ`, `WRITE`, `PRINT`, etc.). The form of the `FORMAT` statement is:

```
FORMAT format_specification
```

When a format specification is given with a `CHARACTER` array or `CHARACTER` expression (`CHARACTER` variables, array elements, and substrings are simple `CHARACTER` expressions) it appears as a format specifier in the cilist of data transfer statements as described later in this chapter. An array name not qualified by subscripts produces a format specification which is the concatenation of all of the elements of the array. Leading and trailing blanks within the `CHARACTER` item are not significant.

A format specification is given with an opening parenthesis, an optional list of edit descriptors, and a closing parenthesis. A format specification may be given within a format specification; that is, it may be nested. When a format specification is given in this manner it is called a group specifier and can be given a repeat count, called the group repeat count, which is a positive `INTEGER` constant immediately preceding the opening parenthesis. The maximum level of nesting is 20.

The edit descriptors define the fields of a record and are separated by commas except between a `P` edit descriptor and an `F`, `E`, `D`, or `G` edit descriptor and before or after slash and colon edit descriptors (see below). The fields defined by edit descriptors have an associated width, called the field width.

An edit descriptor is either repeatable or nonrepeatable. Repeatable means that the edit descriptor is to be used more than once before going on to the next edit descriptor in the list. The repeat factor is given immediately before the edit descriptor as a positive integer constant.

The repeatable edit descriptors and their meanings are:

<code>Iw</code> and <code>Iw.m</code>	integer editing
<code>Bw</code> and <code>Bw.m</code>	binary editing
<code>Aw</code> and <code>Aw.m</code>	octal editing
<code>Zw</code> and <code>Zw.m</code>	hexadecimal editing
<code>Fw.d</code>	floating point editing
<code>EW.d</code> and <code>EW.dEe</code>	single precision scientific editing
<code>Dw.d</code>	double precision scientific editing
<code>ENw.d</code> and <code>EW.dEe</code>	single precision engineering editing
<code>ESw.d</code> and <code>EW.dEe</code>	single precision scientific editing
<code>Gw.d</code> and <code>Gw.dEe</code>	general floating point editing
<code>Lw</code>	logical editing
<code>A[w]</code>	character editing

w and e are nonzero, unsigned, integer constants and d and m are unsigned integer constants.

The nonrepeatable edit descriptors and their meanings are:

<code>'h1 h2 ... hn'</code>	character string
<code>nHh1 h2 ... hn</code>	Hollerith string
<code>nX</code>	skip positions
<code>TC, TlC, and TRC</code>	tab to column
<code>kP</code>	set scale factor
<code>/</code>	start a new record
<code>:</code>	conditionally terminate I/O
<code>S, SP, and SS</code>	set sign control
<code>BZ and BN</code>	set blank control
<code>\$ or \</code>	suppress end of record
<code>Q</code>	return count of characters remaining in current record
<code>"h1 h2 ... hn"</code>	character string

h is an ASCII character; n and c are nonzero, unsigned, integer constants; and k is an optionally signed integer constant.

FORMAT AND I/O LIST INTERACTION

During formatted data transfers, the I/O list items and the edit descriptors in the format specification are processed in parallel, from left to right. The I/O list specifies the variables that are transferred between memory and the fields of a record, while the edit descriptors dictate the conversions between internal and external representations.

The repeatable edit descriptors control the transfer and conversion of I/O list items. A repeatable edit descriptor or format specification preceded by a repeat count, r , is treated as r occurrences of that edit descriptor or format specification. Each repeatable edit descriptor controls the transfer of one item in the I/O list except for complex items which require two F, E, D, or G edit descriptors. A complex I/O list item is considered to be two real items.

The nonrepeatable edit descriptors are used to manipulate the record. They can be used to change the position within the record, skip one or more records, and output literal strings. The processing of I/O list items is suspended while nonrepeatable edit descriptors are processed.

If the end of the format specification is reached before exhausting all of the items in the I/O list, processing starts over at the beginning of the last format specification encountered and the file is positioned to the beginning of the next record. The last format specification encountered may be a group specifier, if one exists, or it may be the entire format specification. If there is a repeat count in front of a group specifier it is also reused.

INPUT VALIDATION

Before numeric conversion from external to internal values using a format specification, input characters will be checked to assure that they are valid for the specified edit descriptor.

Valid input under the **I** edit descriptor:

digits: 0, 1, 2, 3, 4, 5, 6, 7, 8, 9
characters: +, -

Valid input under the **B** edit descriptor:

digits: 0, 1

Valid input under the **O** edit descriptor:

digits: 0, 1, 2, 3, 4, 5, 6, 7

Valid input under the **Z** edit descriptor:

digits: 0, 1, 2, 3, 4, 5, 6, 7, 8, 9
characters: A, B, C, D, E, F, a, b, c, d, e, f

Valid input under the **F**, **E**, **D**, and **G** edit descriptors:

digits: 0, 1, 2, 3, 4, 5, 6, 7, 8, 9
characters: E, D, e, d, +, -, .

The appearance of any character not considered valid for a particular edit descriptor will generate a runtime error. However, the appearance of a valid character in an invalid position will not result in an error. If the `ERR=` I/O specifier was present in the input statement generating the error, control will be transferred to the specified line number. If the `IOSTAT=` I/O specifier was present in the input statement generating the error, the specified variable will be defined with the error code.

INTEGER EDITING

The **B**, **O**, **Z** and **I** edit descriptors control the translation of character strings representing integer values to and from the appropriate internal formats.

I Editing

The `Iw` and `Iw.m` edit descriptors must correspond to an integer I/O list item. The field width in the record consists of *w* characters.

On input, the I/O list item will be defined with the value of the integer constant in the input field which may have an optional leading sign.

The output field consists of a string of digits representing the integer value which is right justified and may have a leading minus sign if the value is negative. If m is specified, the string will consist of at least m digits with leading zeros as required. The output field will always contain at least one digit unless an m of zero is specified in which case only blank characters will be output. If the specified field width is too small to represent the integer value, the field is completely filled with the asterisk character.

```
      WRITE (*,10) 12, -12, 12
10    FORMAT (2I4,I6.4)

      12 -12  0012
```

B, O, and Z Editing

The B, O, and Z edit descriptors are specified in the same manner as the I edit descriptor and perform bit editing on binary, octal, and hexadecimal fields respectively. The field width in the record consists of w characters. An input list item can be up to thirty-two bits in length and may have a LOGICAL, INTEGER, REAL, or COMPLEX data type. An output list value can be no longer than thirty-two bits in length and may have a LOGICAL, INTEGER, REAL, or COMPLEX data type. (Note that COMPLEX data requires two edit descriptors per data item).

On input, the I/O list item will be defined with the binary representation of the external value.

The output field consists of a string of characters representing the value and is right justified. If m is specified, the string will consist of at least m digits with leading zeros as required. The output field will always contain at least one digit unless an m of zero is specified in which case only blank characters will be output.

```
      WRITE (*,10) 199, 199, 199
10    FORMAT (Z4,O7.6,B9)

      C7 000307 11000111
```

FLOATING POINT EDITING

The F, E, D, and G edit descriptors control the translation of character strings representing floating point values (REAL, DOUBLE PRECISION, and COMPLEX) to and from the appropriate internal formats. The edit descriptor must correspond to a floating point I/O list item. On input, the I/O list item will be defined with the value of the floating point constant in the input field.

A complex value consists of a pair of real values and consequently requires two real edit descriptors.

F Editing

The field width of the $F_{w.d}$ edit descriptor consists of w characters. The fractional portion, if any, consists of d characters. If the specified field width is too small to represent the value, the field is completely filled with the asterisk character.

The input field consists of an optional sign and a string of digits which can contain a decimal point. This may be followed by an exponent which takes the form of either a signed integer constant or the letter **E** or **D** followed by an optionally signed integer constant.

The output field consists of a minus sign if the value is negative and a string of digits containing a decimal point with d fractional digits. The value is rounded to d fractional digits and the string is right justified in the field. The position of the decimal point may be modified by the scale factor as described under the kP edit descriptor.

```

      WRITE (*,10) 1.23, -1.23, 123.0, -123.0
10    FORMAT (2F6.2,F6.1,F6.0)

      1.23 -1.23 123.0 -123.

```

E and D Editing

The field width of the $E_{w.d}$, $E_{w.dEe}$, and $D_{w.d}$ edit descriptors consists of w characters in scientific notation. d specifies the number of significant digits. If e is specified, the exponent contains e digits, otherwise, the exponent contains two digits for **E** editing and three digits for **D** editing.

The input field is identical to that specified for **F** editing.

The output field consists of a minus sign if the value is negative, a zero, a decimal point, a string of d digits, and an exponent whose form is specified in the table below. The value is rounded to d fractional digits and the string is right justified in the field. The position of the decimal point may be modified by the scale factor as described under the kP edit descriptor.

<u>Edit Descriptor</u>	<u>Absolute value of Exponent</u>	<u>Form of Exponent</u>
$E_{w.d}$	≤ 99	$E\pm nn$
$E_{w.d}$	$100 - 999$	$\pm nnn$
$E_{w.dEe}$	$\leq (10^e) - 1$	$E\pm n_1n_2...n_e$
$D_{w.d}$	≤ 99	$D\pm nn$
$D_{w.d}$	$100 - 999$	$\pm nnn$

```

      WRITE (*,10) 1.23, -1.23, -123.0E-6, .123D3
10    FORMAT (2E12.4,E12.3E3,D12.4)

      0.1230E+01 -0.1230E+01 -0.123E-003  0.1230D+03

```

EN Editing

The `ENw.d` and `ENw.dEe` edit descriptors produce engineering notation where the decimal exponent is divisible by 3 and the integer portion is greater than or equal to 1 and less than 1000. The input field is identical to that specified for `F` editing.

```
PRINT "(EN15.3)", 5.79642, -100221.0, 0.008554

      5.796E+00
     -100.221E+03
      8.554E-03
```

ES Editing

The `ENw.d` and `ENw.dEe` edit descriptors produce engineering notation where the decimal integer portion is greater than or equal to 1 and less than 10. The input field is identical to that specified for `F` editing.

```
PRINT "(ES15.3)", 5.79642, -100221.0, 0.008554

      5.796E+00
     -1.002E+05
      8.554E-03
```

G Editing

The `Gw.d` and `Gw.dEe` edit descriptors are similar to the `F` and `E` edit descriptors and provide a flexible method of accomplishing output editing.

The input field is identical to that specified for `F` editing.

The form of the output field depends on the magnitude of the value in the I/O list. `F` editing will be used unless the value of the item would cause the field width to be exceeded in which case `E` editing is used. In both cases, the field consists of w right justified characters.

<u>Magnitude of N</u>	<u>Equivalent Conversion</u>
$N < 0.1$	<code>E_w.d</code>
$0.1 < N < 1.0$	<code>F(w-4).d, 4X</code>
$1.0 < N < 10.0$	<code>F(w-4).(d-1), 4X</code>
.	.
:	:
.	.
$10^{d-2} < N < 10^{d-1}$	<code>F(w-4).1, 4X</code>
$10^{d-1} < N < 10^d$	<code>F(w-4).0, 4X</code>
$N > 10^d$	<code>E_w.d[Ee]</code>

```
      WRITE (*,10) 1.0, 10.0, 100.0, 1000.0, 10000.0
10    FORMAT (5G10.4)

      1.000      10.00      100.0      1000.      0.1000E+05
```

P Editing

The kP edit descriptor is used to scale floating point values edited with the F, E, D, and G edit descriptors. k is called the scale factor and is given as an integer constant which may be negative, positive, or zero. The scale factor starts at zero for each formatted I/O statement.

If there is an exponent in the input field, the scale factor has no effect, otherwise the external value is equal to the internal value multiplied by 10^k .

For output with F editing, the effect of the scale factor is the same as described for input. For E and D editing, the scale factor is used to control decimal normalization of the output value. If k is negative, leading zeros are inserted after the decimal point, the exponent is reduced by k , and $|k|$ significant digits are lost. If k is positive, the decimal point is moved to the right within the d significant digits, the exponent is reduced by k , and no significant digits are lost. The field width remains constant in all cases, meaning that $-d < k < d + 2$.

```
      WRITE (*,10) 1.23, 1.23, 1.23
10    FORMAT (1PF8.4,-1PF8.4,1PE12.4)

      12.3000      .1230      1.2300E+00
```

CHARACTER AND LOGICAL EDITING

The A and L edit descriptors control the translation of character strings representing CHARACTER and LOGICAL values to and from the appropriate internal formats.

A Editing

The $A[w]$ edit descriptor is used to copy characters (bytes) to and from I/O list items. If present, w specifies the field width; otherwise the field width is the same as the length of the I/O list item. The only editing performed is to space fill or truncate for input and output respectively.

For input, when w is less than the length of the I/O list item, the characters from the field are left justified and space filled to the length of the item. When w is equal to or greater than the length of the I/O list item, the rightmost characters in the field are used to define the item.

For output, when w is less than or equal to the length of the I/O list item, the field will contain the leftmost w characters of the item. When w is greater than the length of the I/O list item, the item is right justified in the field with leading spaces added as necessary.

```

      WRITE (*,10) 'HELLO, WORLD ', ' ', 'WORLD'
10    FORMAT (A5,A,A6)

HELLO, WORLD

```

L Editing

The L_w edit descriptor must correspond to a logical I/O list item. The field width in the record consists of w characters.

The input field consists of an optional decimal point and either the letter T (`.TRUE.`) or F (`.FALSE.`). Other characters may follow, but they do not take part in determining the LOGICAL value. The field may contain leading spaces.

The output field is right justified and contains either the letter T or F representing the values `.TRUE.` and `.FALSE.`, respectively.

```

      WRITE (*,10) .TRUE., .FALSE.
10    FORMAT (2L2)

  T  F

```

SIGN CONTROL EDITING

The `S`, `SP`, and `SS` edit descriptors control the output of optional plus signs. Normally, a leading plus sign is not output for positive numeric values. The `SP` edit descriptor forces a plus sign to appear in the output field. The `S` and `SS` edit descriptors return the processing of plus signs to the default state of not being output.

```

      WRITE (*,10) 123, -123, 123.0, -123.0, 123.0
10    FORMAT (SP,2I5,2F7.1,SS,F7.1)

+123 -123 +123.0 -123.0 123.0

```

BLANK CONTROL EDITING

The `BN` and `BZ` edit descriptors control the processing of blanks in numeric input fields which can be interpreted either as nulls or zeros. The default for an individual file connection is established with the “`BLANK=`” specifier. If the specifier does not appear in an `OPEN` statement blanks are treated as nulls. The `BN` edit descriptor causes blanks to be treated as nulls and the `BZ` edit descriptor causes blanks to be treated as zeros.

POSITIONAL EDITING

The `X`, `T`, and `/` edit descriptors are used to control the position within the record and the position within the file.

X Editing

The `nX` edit descriptor moves the position within the record `n` characters forward. On input `n` characters are bypassed in the record. On output `n` blanks are output to the record.

```
        WRITE (*,10) -123, -123.0
10      FORMAT (I4,1X,F6.1)

-123 -123.0
```

T, TL, and TR Editing

On output, the entire record is first filled with spaces. The `TC`, `TLC`, and `TRC` edit descriptors are also used to move the position within the record, but in a non-destructive manner. This is called tabbing. Position means character position with the first character in the record being at position one. Changing the position within the record does change the length of the record.

The `TC` edit descriptor moves to absolute position `C` within the record. The `TLC` and `TRC` edit descriptors move to positions relative to the current position. `TRC` moves the position `C` characters to the right and `TLC` moves the position `C` characters to the left. `C` is a positive integer constant.

```
        WRITE (*,10) 89, 567, 23, 1, 4
10      FORMAT (T8,I2,TL5,I3,T2,I2,TL3,I1,TR2,I1)

123456789
```

Slash Editing

The `/` edit descriptor positions the file at the beginning of the next record. On input it skips the rest of the current record. On output it creates a new record at the end of the file.

The `/` edit descriptor can be used to skip entire records on input or to write empty records on output. Empty records in internal or direct access files are filled with blanks.

When the / edit descriptor is used with files connected for direct access it causes the record number to be increased and data transfer will be performed with that record.

```

      WRITE (*,10) (A, A=1.0,10.0)
10    FORMAT (5F5.1,/,5F5.1)

      1.0  2.0  3.0  4.0  5.0
      6.0  7.0  8.0  9.0 10.0

```

Dollar Sign and Backslash Editing

The \$ and \ edit descriptors are interchangeable and are used to suppress the normal output of end of record characters in formatted records. When one of these edit descriptors appears in a format list, the output of end of record characters will be suppressed for the remainder of the I/O statement.

COLON EDITING

The : edit descriptor is used to terminate a formatted I/O statement if there are no more data items to process. For example, the : edit descriptor could be used to stop positional editing when there are no more items in the I/O list.

APOSTROPHE AND HOLLERITH EDITING

Apostrophe and Hollerith edit descriptors are used to copy strings of characters to the output record. These edit descriptors may only be used with the WRITE, PRINT and TYPE statements.

Apostrophe Editing

An apostrophe edit descriptor takes exactly the same form as a character constant as described in **The Fortran Program** chapter. The field width is equal to the length of the string.

```

      WRITE (*,10)
10    FORMAT ('APOSTROPHE',1X,'EDIT FIELDS')

      APOSTROPHE EDIT FIELDS

```

H Editing

The n_H edit descriptor takes exactly the same form as a Hollerith constant as described in the chapter **The Fortran Program**. The field width is equal to the positive integer constant, n , which defines the length of the Hollerith constant.

```
        WRITE (*,10)
10      FORMAT (15HHOLLERITH EDIT ,6HFIELDS)

HOLLERITH EDIT FIELDS
```

Q EDITING

The `Q` edit descriptor obtains the number of characters remaining in the current input record and assigns it the corresponding I/O list element. The I/O list element must be four byte integer variable. The `Q` edit descriptor has no effect on output except that the corresponding I/O list item is skipped.

```
        READ (*,10) I, (CHRS(J),J=1,I)
10      FORMAT (Q,80A1)
```

This example uses the `Q` edit descriptor to determine the number of characters in a record and then reads that many characters into the array `CHRS`.

VARIABLE FORMAT EXPRESSIONS

Variable format expressions allow you to use an arithmetic expression enclosed in angle brackets wherever an integer would normally be used in a `FORMAT` statement, with exception of the number of characters in a `H` (Hollerith constant) field. For example:

```
1000 FORMAT (I<N+4>)
```

The variable format expression, `N+4`, is scanned at runtime each time the `FORMAT` is used. If necessary, the expression is first converted to integer. The expression may contain function references. If side effects of the I/O statement cause the value of the expression to change, the value before the execution of the I/O statement is used.

LIST DIRECTED EDITING

List directed editing is indicated with an asterisk (*) as a format specifier. List directed editing selects editing for I/O list items appropriate to their data type and value. List directed editing treats one or more records in a file as a sequence of values delimited by value separators. A value separator is one or more blanks, a comma, a slash, or an end of record. Blanks can precede and follow the comma and slash separators. Except within a quoted character constant, multiple blanks and end of record characters are treated as a single blank character. An end of record occurring within a quoted character constant is treated as a null.

Tabs are expanded modulo eight by default; other tab sizes can be used by setting an environment variable. Refer to your system documentation for instructions on modifying this system dependent variable.

The values are either constants, nulls, or one of the forms:

$$r^*c$$
$$r^*$$

where r is an unsigned, nonzero, integer constant. The first form is equivalent to r occurrences of the constant c , and the second is equivalent to r nulls. Null items are defined by having no characters where a value would be expected, that is, between successive separators or before the first separator in a record.

List Directed Input

A character value is a string of characters between value separators. If the string is quoted embedded blanks are significant and the value can span more than one record. The corresponding I/O list item is defined with the value as though a character assignment statement was performed; left justified and truncated or blank filled as necessary.

Any form suitable for an `I` edit descriptor can be used for list directed input of an `INTEGER` item.

Any form suitable for an `L` edit descriptor can be used for list directed input of a `LOGICAL` item. In particular, `.TRUE.` and `.FALSE.` are acceptable.

`DOUBLE PRECISION` and `REAL` input is performed with the effect of a `Fw.0` edit descriptor where w is the number of characters in the constant. The value can be in any form acceptable to the `F` edit descriptor.

A `COMPLEX` constant must have an opening parenthesis, a floating point constant as described above, a comma, another floating-point constant, and a closing parenthesis. Leading and trailing spaces are permitted around the comma. The first constant represents the real portion of the value and the second constant represents the imaginary portion.

Null values have no effect on the corresponding I/O list items; their definition status will not change.

A slash in the input record terminates a list directed input statement. Any unprocessed I/O list items will be left unchanged.

List Directed Output

With the exception of `CHARACTER` constants, all output items are separated by a single blank that is generated as part of the string.

`CHARACTER` output is performed using an `A` edit descriptor. There is no leading blank.

`LOGICAL` output is performed using an `L2` edit descriptor.

INTEGER output is performed using an `Iw` edit descriptor where *w* is one digit greater than the number of digits required to represent the value.

DOUBLE PRECISION and REAL output is performed using `1PG15.6E2` and `1PG24.15E3` edit descriptors respectively.

COMPLEX output consists of an opening parenthesis, the real portion of the value, a comma, the imaginary portion of the value, and a closing parenthesis. The numeric portions are formatted with descriptors that match the precision of the data as above.

NAMELIST DIRECTED EDITING

Namelist directed editing, an extension to standard Fortran, allows a number of variables to be treated as a group for the purpose of data transfer. Its use is restricted to formatted external files that have been connected for sequential access. Namelist directed editing selects editing for a namelist group member based on its type and value. Namelist directed editing treats one or more records as a group, where each group contains a series of group-member/value(s) combinations.

Namelist Directed Input

Namelist directed input reads external records until it finds the specified namelist group. It then assigns data to the specified group members in the order they are encountered. Group members which are not specified retain their previous values.

Namelist directed input has the following form:

```
$group member=value, [member=value, ...] $END
```

where: `$` is used to delimit the start and end of a particular group. The ampersand (`&`) can also be used for this purpose. The slash (`/`) can also be used to delimit the end of input for a given namelist group.

group is the symbolic name of a namelist previously defined in the program unit. The name cannot contain spaces or tabs.

member is a namelist defined variable. It may be a scalar, an array name, an array element name, a substring, or an array name with a substring. The member name cannot contain spaces or tabs. Subscript and substring specifiers must be integer constants. Use of symbolic (PARAMETER) constants is not allowed.

value is a constant, a list of constants, or a repetition of constants of the form *r*c*. Valid separators for value constants are spaces, tabs, and commas. A null value is specified by two consecutive commas, a leading comma, or a trailing comma. The form *r** indicates *r* null values.

Character constants must be delimited by apostrophes or quotation marks. Occurrences of a character delimiter within the delimited string are represented by two consecutive occurrences of the delimiter. The end of record character is equivalent to a single space unless it occurs in a character constant, in which case it is ignored and the character constant is assumed to continue on the next record. Hollerith, binary, octal, and hexadecimal constants are not permitted.

END is an optional part of the terminating delimiter.

Group and member names are not case sensitive and are folded to upper case before use. Consider the following example:

```
INTEGER*4 INT,int
NAMELIST /NLIST/INT,int
...
READ (*,NML=NLIST)
```

where the input looks like:

```
$NLIST
INT = 12,
int = 15,
$END
```

Because namelist input is not case sensitive, execution of the read statement will cause INT to take on the value 15 and the value of int will be unchanged.

Conversion of external to internal representations is performed using the same editing as list directed input.

It is not necessary to assign values to all members of a namelist group. Group members not specified in the input retain their previous values. For namelist input of subscripted arrays and substring, only the values of the specified array elements and substrings are changed. Input containing group-members which are not actually members of the group is not permitted.

When namelist input is performed using an asterisk for the unit specifier, the group-name is written to standard out and the program waits for input from standard in.

An example of namelist directed input follows:

```
NAMELIST /WHO/NAME, CODE, NEW, RATIO, UNCHANGED
CHARACTER*8 NAME
INTEGER*4 CODE(4)
LOGICAL*4 NEW
REAL*4 RATIO, UNCHANGED
OPEN(10, FILE='INFO', FORM='FORMATTED', ACCESS='SEQUENTIAL')
READ(UNIT=10, NML=WHO)
```

where the input file test contains:

```
$WHO  
NAME      = 'John Doe',  
CODE(3)   = 12,13,  
NEW       = .TRUE.,  
RATIO     = 1.5,  
$END
```

The `NAMelist` statement in this example creates a group named `WHO` with the members `NAME`, `CODE`, `NEW`, `RATIO`, and `UNCHANGED`. The `READ` statement then assigns values to the group members which are present in the input file. After execution of the `READ` statement, the variables `NAME`, `NEW`, and `RATIO` will have the values specified in the input. Because the array `CODE` has been subscripted, value assignment will begin with element three and continue until a new group-member name is encountered. As a result, elements 3 and 4 will be assigned the values 12 and 13 respectively. Elements 1 and 2 retain their previous values. Since the variable `UNCHANGED` does not appear in the input, it will retain whatever value it had before execution of the `READ` statement.

Namelist Directed Output

Namelist directed output transfers the current values of all members of a namelist group. The values are written in a form acceptable for namelist input. The group and group member names will be converted to upper case before being output. The order in which the values are written is determined by the order in which the group members appear in the `NAMelist` statement. An example of namelist output follows:

```
INTEGER ONE,TWO  
CHARACTER*10 ALPHA  
NAMelist /NLIST/ONE,TWO,ALPHA  
ONE = 10  
TWO = 20  
ALPHA = 'ABCDEFGHJIJ'  
OPEN(10,FILE='TEST',ACCESS='SEQUENTIAL',FORM='FORMATTED')  
WRITE(UNIT=10,NML=NLIST)  
...
```

The `WRITE` statement produces the following output:

```
$NLIST  
ONE      = 10,  
TWO      = 20,  
ALPHA    = 'ABCDEFGHJIJ',  
$END
```

CHAPTER 9

Programs, Subroutines, and Functions

There are seven types of procedures available in Absoft Fortran 77: main programs, subroutines, external functions, internal procedures, statement functions, intrinsic functions, BLOCK DATA subprograms.

The main program is the entry point of a Fortran program. The compiler does not require that the main program occurs first in the source file, however, every Fortran program must have exactly one main program.

Subroutines and external functions are procedures that are defined outside of the program unit that references them. They may be specified either in separate Fortran subprograms or by means other than Fortran such as assembly language or the C programming language.

An internal procedure is a subroutine or function that is defined inside an external procedure. An internal procedure may only appear after a CONTAINS statement and must end with either END SUBROUTINE or END FUNCTION. An internal procedure automatically **has access to all of the host's entities**, including variables, dummy arguments, and other internal procedures.

BLOCK DATA subprograms are nonexecutable procedures that are used to initialize variables and array elements in named COMMON blocks. There may be several block data subprograms in a Fortran program.

PROGRAMS

A main program is defined in the following manner:

```
[PROGRAM program-name]
  [specification-statements]
  [executable-statements]
[CONTAINS
  internal-procedures]
END [PROGRAM [program-name]]
```

The PROGRAM statement is not required to be present in a Fortran program. If it is present it must be the first line of the main program unit.

SUBROUTINES

A subroutine is an external procedure that is defined external to the program unit that references it and is specified in a subroutine subprogram. A subroutine may be referenced within any other procedure of the executable program.

A subroutine subprogram is defined in the following manner:

```
SUBROUTINE name ([dummy-arguments])  
  [specification-statements]  
  [executable-statements]  
[CONTAINS  
  internal-procedures]  
END [SUBROUTINE [name]]
```

where: *name* is a unique symbolic name that is used to reference the subroutine.

(dummy-arguments) is an optional comma separated list of variable names, array names, dummy procedure names, or asterisks that identifies the dummy arguments that are associated with the actual arguments in the referencing statement.

A subroutine is referenced with a `CALL` statement that has the form:

```
CALL sub ([actual-arguments])
```

where: *sub* is the symbolic name of a subroutine or dummy procedure.

([actual-arguments]) is the comma separated list of actual arguments that are associated with the arguments in the SUBROUTINE statement.

Subroutine Arguments

The argument lists of `CALL` and `SUBROUTINE` statements have a one to one correspondence; the first actual argument is associated with the first dummy argument and so on. The actual arguments in a `CALL` statement are assumed to agree in number and type with the dummy arguments declared in the `SUBROUTINE` statement. No type checking is performed by the compiler or the run time system to insure that this assumption is followed.

The addresses of labeled statements may be passed to subroutines by specifying the label preceded by an asterisk in the actual argument list and specifying an asterisk only in the corresponding position in the dummy argument list of the `SUBROUTINE` statement. This allows you to return to a location in the calling procedure other than the statement that immediately follows the `CALL` statement (see `RETURN` below).

Dummy procedure names allow you pass the names of procedures to other subprograms. The dummy procedure name can then be referenced as though it were the actual name of an external procedure.

FUNCTIONS

A function returns a value to the point within an expression that references it. An external function is specified in a separate procedure called a function subprogram. A statement function is defined in a single statement within a program unit and is local to that program unit. Intrinsic functions are library procedures provided with the Fortran environment and are available to any program unit in an executable program. A function name may not be used on the left side of an equals sign except for an external function name and then only within the program unit that defines it.

A function reference is made in the form of an operand in an expression. The function name is given with an argument list enclosed in parentheses. The parentheses must be used even if there are no arguments to the function so that the compiler can determine that a function reference is indeed being made and not simply a reference to a variable.

External Functions

An external function may be referenced within any other procedure in an executable program. Character functions must be declared with integer constant lengths so that the compiler can determine the size of the character value that will be returned.

The form of a function subprogram declaration is:

```
[type [*len]] FUNCTION func ([arg] [,arg]...)
```

where: *func* is a unique symbolic name that is used to reference the function.

([*arg*] [,*arg*]...) is an optional list of variable names, array names, or dummy procedure names that identifies the dummy arguments that are associated with the actual arguments in the referencing statement.

As indicated, the function can be given an optional type and length attribute. This can be done either explicitly in the `FUNCTION` statement or in a subsequent type statement, or implicitly following the data typing rules described in **The Fortran Program** chapter. Note that an `IMPLICIT` statement may change the data type and size.

When a `CHARACTER` function is given a length attribute of `*(*)` it assumes the size established in the corresponding character declaration in the referencing program unit.

The symbolic name used to define the function must be assigned a value during the execution of the function subprogram. It is the value of this variable that is returned when a RETURN or END statement is executed.

A function (external or internal) can return a pointer:

```
integer, dimension(10) :: m = (/123, 87, 55, 203, 88, &  
                               908, 13, 792, 66, 118/)  
integer, dimension(:), pointer :: p
```

```
p => pick(m, 100)  
print *,p
```

contains

```
function pick(m, limit)  
  integer, dimension(:), pointer :: pick  
  integer, dimension(:) :: m  
  j = 0  
  do i=1,size(m)  
    if (m(i) >= limit) j = j+1  
  end do  
  allocate (pick(j))  
  j = 0  
  do i=1,size(m)  
    if (m(i) >= limit) then  
      j = j+1  
      pick(j) = m(i)  
    end if  
  end do  
end function pick  
  
end
```

```
123 203 908 792 118
```

Statement Functions

A statement function is specified with a single statement that may appear only after the declaration section and before the executable section of the program unit in which it is to be used. A statement function is defined in the following manner:

$$func ([arg[,arg]...]) = e$$

where: *func* is the name that is used to reference the function.

$([arg[,arg]...])$ is the dummy argument list, and *e* is an expression using the arguments from the dummy argument list.

The dummy argument names used in the statement function argument list are local to the statement function and may be used elsewhere in the program unit without conflict.

A statement function must not contain a forward reference to another statement function. The compilation of a statement function removes the symbolic name of the function from the list of available names for variables and arrays within the program unit in which it is defined. Any variable or array that is defined in a program unit may not be redefined as a statement function.

CHARACTER statement functions may not use the `*(*)` length specifier.

Intrinsic Functions

Intrinsic functions contained in the math library do not follow the typing rules for user defined functions and cannot be altered with an `IMPLICIT` statement. The types of these functions and their argument list definitions appear in the next chapter, **Intrinsic Procedures**.

RECURSION

Normally, a function or subroutine may not reference itself, either directly or indirectly. Such a reference would be recursive. The `RECURSIVE` keyword allows such direct or indirect self referencing statements.

```
RECURSIVE FUNCTION
RECURSIVE SUBROUTINE
```

The function $N! = N \times (N-1) \dots 2 \times 1$ lends itself to recursive programming.

```
INTEGER RECURSIVE FUNCTION Factorial(n) RESULT(r)
  IF (n == 1) THEN
    r = 1
  ELSE
    r = n*Factorial(n-1)
  END IF
END FUNCTION Factorial
```

PURE PROCEDURES

The `PURE` keyword is used with functions and subroutines to indicate that the procedure has no side effects. A pure procedure cannot perform I/O operations, contains no variable with a `SAVE` attribute, does not alter variables accessed by host or use association, does not contain a `STOP` statement, and if a function does not alter any dummy argument.

```
PURE FUNCTION AREA(T)
```

ELEMENTAL PROCEDURES

Elemental intrinsic procedures are those with scalar dummy arguments that return scalar results. They can be called with array arguments to return an array result of the same

shape. The `ELEMENTAL` keyword can be used to produce non-intrinsic procedures with the same characteristics.

```
ELEMENTAL FUNCTION AREA(T)
```

An elemental procedure is automatically a pure procedure. All dummy arguments must be scalar without a `POINTER` attribute.

ENTRY STATEMENT

The `ENTRY` statement may only be used within subroutine and function subprograms and provides for multiple entry points into these procedures. The form of an `ENTRY` statement is the same as that for a `SUBROUTINE` statement except that the keyword `ENTRY` is used. An `ENTRY` statement appearing within a `FUNCTION` subprogram may appear in a type statement. An `ENTRY` statement may not occur within any block structure (`DO`, `IF`, or `CASE`).

In a function subprogram, a variable name that is used as the entry name must not appear in any statement that precedes the appearance of the entry name except in a type statement. All function and entry names in a function subprogram share an equivalence association.

Entry names used in character functions must have a character data type and the same size as the name of the function itself.

RETURN STATEMENT

The `RETURN` statement ends execution in the current subroutine or function subprogram and returns control of execution to the referencing program unit. The `RETURN` statement may only be used in function and subroutine subprograms. Execution of a `RETURN` statement in a function returns the current value of the function name variable to the referencing program unit. The `RETURN` statement is given in the following manner:

```
RETURN [e]
```

where: `e` is an `INTEGER` expression allowed only in subroutine `RETURN` statements and causes control to be returned to a labeled statement in the calling procedure associated with an asterisk in the dummy argument list. The first alternate return address corresponds to the first asterisk, the second return address to the second asterisk, etc. If the value of `e` is less than one or greater than the number of asterisks, control is returned to the statement immediately following the `CALL` statement.

PASSING PROCEDURES IN DUMMY ARGUMENTS

When a dummy argument is used to reference an external function, the associated actual argument must be either an external function or an intrinsic function. When a dummy argument is associated with an intrinsic function there is no automatic typing property. If a dummy argument name is also the name of an intrinsic function then the intrinsic function corresponding to the dummy argument name is removed from the list of available intrinsic functions for the subprogram.

If the dummy argument is used as the subroutine name of a `CALL` statement then the name cannot be used as a variable or a function within the same program unit.

PASSING RETURN ADDRESSES IN DUMMY ARGUMENTS

If a dummy argument is an asterisk, the compiler will assume that the actual argument is an alternate return address passed as a statement label preceded by an asterisk. No check is made by the compiler or by the run time system to insure that the passed parameter is in fact a valid alternate return address.

COMMON BLOCKS

A `COMMON` block is used to provide an area of memory whose scoping rules are greater than the current program unit. Because association is by storage offset within a known memory area, rather than by name, the types and names of the data elements do not have to be consistent between different procedures. A reference to a memory location is considered legal if the type of data stored there is the same as the type of the name used to access it. However, the compiler does not check for consistency between different program units and `COMMON` blocks.

The total amount of memory required by an executable program can be reduced by using `COMMON` blocks as a sharable storage pool for two or more subprograms. Because references to data items in common blocks are through offsets and because types do not conflict across program units, the same memory may be remapped to contain different variables.

BLOCK DATA

A `BLOCK DATA` statement takes the following form:

```
BLOCK DATA [sub]
```

where: *sub* is the unique symbolic name of the block data subprogram.

There may be more than one named `BLOCK DATA` subprogram in a Fortran program, but only one unnamed block data subprogram.

Only `COMMON`, `SAVE`, `DATA`, `DIMENSION`, `END`, `EQUIVALENCE`, `IMPLICIT`, `PARAMETER`, and type declaration statements may be used in a `BLOCK DATA` subprogram.

CHAPTER 10

INTRINSIC PROCEDURES

This chapter is devoted to summarizing and categorizing Fortran's intrinsic procedures: intrinsic functions and intrinsic subroutines. This summary has ten categories of procedure, each with certain similar characteristics, and ends with a concise alphabetical listing of all intrinsic procedures and their arguments. Each intrinsic procedure is described more fully, in alphabetical order, in the last section of this chapter.

INTRINSIC PROCEDURE SUMMARY

numeric inquiry functions

digits	significant digits (e.g., bits) for a given integer or real kind
epsilon	a small value (small compared to 1) for a given real kind
exponent	the exponent value for a given real value
fraction	the fractional part of a given real value
huge	the largest value representable for a given real or integer kind
minexponent	the minimum exponent value for a given real kind
maxexponent	the maximum exponent value for a given real kind
nearest	the processor value nearest to a given real value, in a given direction
precision	the decimal precision of a given real or complex kind
radix	numeric base (typically binary) for a given real or integer kind
rrspacing	reciprocal of the relative spacing near a given real value
range	the decimal exponent range of a given numeric kind
scale	change the exponent of a given real value by a specified amount
set_exponent	set the exponent of a given real value to the specified amount
spacing	the absolute spacing near a given real value
tiny	the smallest positive value representable for a given real kind

array inquiry functions

allocated	true if the given array is currently allocated (false otherwise)
lbound	lower bound(s) of a given array or a given dimension of an array
shape	the number of elements in each dimension of a given array
size	the size (total number of elements) of a given array
ubound	upper bound(s) of a given array or a given dimension of an array

miscellaneous inquiry functions

associated	true if the given pointer is currently allocated (false otherwise)
bit_size	the number of bits (for bit computations) in a given integer kind
command_argument_count	the number command line arguments
kind	the value of the kind type parameter of a given data entity
len	the number of characters in a given string value
present	true if there is an actual argument for a given optional dummy argument
selected_int_kind	the integer kind for a given integer decimal range
selected_real_kind	the real kind for a given decimal precision and range

conversion functions

achar	the character in the specified position of the ASCII character set
aimag	the imaginary part of a given complex value
aint	a given real value truncated to an integer (result is still real)
anint	a given real value rounded to the nearest integer (result is still real)
char	the character in the specified position of the processor character set
cmplx	the complex value of a given single or pair of integer or real values
conjg	the complex conjugate of a given complex value
dble	the double precision value of a given numeric value of any type
iachar	position of the specified character in the ASCII character set
ibits	the specified substring of bits of a given integer value
ichar	position of the specified character in the processor character set
int	the (truncated) integer value of a given numeric value of any type
logical	the logical value of specified kind for a given logical value
nint	the (rounded) integer value of a given real value
real	the real value of a given numeric value of any type and kind
transfer	conversion to a specified type without change in the “bit pattern”

numeric computation functions

abs	the absolute value of a given numeric value of any type
acos	the arc cosine (radians) of a given real value
asin	the arc sine (radians) of a given real value
atan	the arc tangent (radians) of a given real value
atan2	the angle (radians) of given real and imaginary components
ceiling	the smallest integer not less than a given real value
cos	the cosine of a given real or complex value (given value in radians)
cosh	the hyperbolic cosine of a given real value
dim	maximum of: zero and the difference of two real or integer values
dot_product	the dot product of two given vectors of numeric or logical type
dprod	the double precision product of two single precision real values
erf	the error function
erfc	the complementary error function
exp	the natural exponential function (real or complex)
floor	the greatest integer not greater than a given real value

log	the natural logarithm function (real or complex)
log10	the logarithm to the base 10 of a given real value greater than zero
matmul	matrix multiplication of two given numeric or logical matrices
max	the maximum of a set of given integer or real values
min	the minimum of a set of given integer or real values
mod	the remainder function, having the sign of the first given value
modulo	the remainder function, having the sign of the second given value
sign	apply a given sign to a given integer or real value
sin	the sine of a given real or complex value (given value in radians)
sinh	the hyperbolic sine of a given real value
sqrt	the square root of a given real or complex value greater than zero
tan	the tangent of a given real value (given value in radians)
tanh	the hyperbolic tangent of a given real value

character computation functions

adjustl	left-justify a given string value in the same-width field
adjustr	right-justify a given string value in the same-width field
index	find the location of a given substring in a given string value
len_trim	length of a given string after trailing blanks have been removed
lge	greater than or equal to ASCII comparison of two given strings
lgt	greater than ASCII comparison of two given string values
lle	less than or equal to ASCII comparison of two given string values
llt	less than ASCII comparison of two given string values
repeat	concatenate several copies of a given string value
scan	search a given string value for any of a given set of characters
trim	remove trailing blank characters from a given string value
verify	position of a character in a string that is not one of a given set

bit computation functions

btest	the bit value of a specified position in a given integer value
band	bit-by-bit AND of two given integer values
ibclr	set to zero the bit in a specified position in a given integer value
ibset	set the bit in a specified position to the specified (0 or 1) value
ieor	bit-by-bit exclusive-OR of two given integer values
ior	bit-by-bit OR of two given integer values
ishft	end-off shift of the bits in a specified integer value
ishftc	circular shift of the bits in a specified integer value
not	bit-by-bit complement of a given integer value

array computation functions

all	true if all of the elements of a given logical array are true
any	true if any of the elements of a given logical array are true
count	the number of true elements in a given logical array
cshift	circular shift the elements of a given array of any type
eoshift	end-off shift the elements of a given array of any type
maxloc	a rank-one array locating the maximum element of a given array
maxval	the maximum element value of a given integer or real array

merge	combines (merges) two arrays under control of a mask
minloc	a rank-one array locating the minimum element of a given array
minval	the minimum element value of a given integer or real array
pack	packs elements of an array into a vector, under control of a mask
product	the product of all elements of a given numeric array of any type
reshape	reshapes a given rank-one array into the specified array shape
spread	replicates an array along a new dimension
sum	the sum of all elements of a given numeric array of any type
transpose	the matrix transpose of a given rank-two array of any type
unpack	unpacks a vector into elements of an array, under control of a mask

intrinsic subroutines

cpu_time	returns processor time
date_and_time	returns date and time information in several formats
get_command	the command line
get_command_argument	a command line argument
get_environment_variable	an environment variable
mvbits	copies a sequence of bits between given integer values
random_number	returns one or more pseudorandom numbers
random_seed	allows setting of the random number generator seed value
system_clock	returns various data from the processor's real-time clock

pointer functions

null	returns a disassociated pointer
-------------	---------------------------------

ALPHABETICAL LISTING OF INTRINSIC PROCEDURES

generic procedure	optional arguments	specific name	specific argument type
abs (a)		abs (a) cabs (a) dabs (a) iabs (a)	real complex double precision integer
achar (i) acos (x)		acos (x) dacos (x)	real double precision
adjustl (string) adjustr (string) aimag (z) aint (a, kind)	kind	aimag (z) aint (a) dint (a)	complex real double precision
all (mask, dim) allocated (array) anint (a, kind)	dim kind	 anint (a) dnint (a)	 real double precision
any (mask, dim)	dim		

generic procedure	optional arguments	specific name	specific argument type
asin (x)		asin (x) dsin (x)	real real precision
associated (pointer, target)	target		
atan (x)		atan (a) dtan (a)	real double precision
atan2 (y, x)		atan2 (a) dtan2 (a)	real double precision
bit_size (i)			
btest (i, pos)			
ceiling (a, kind)	kind		
char (i, kind)	kind		
cmplx (x, y, kind)	y, kind		
command_argument_count()			
conjg (z)		conjg (x)	complex
cos (x)		cos (x) ccos (x) dcos (x)	real complex double precision
cosh (x)		cosh (x) dcosh (x)	real double precision
count (mask, dim)	dim		
cshift (array, shift, dim)	dim		
date_and_time (date, time, zone, values)	date, time, zone, values		
dbble (a)			
digits (x)			
dim (x, y)		dim (x,y) idim (x,y) ddim (x,y)	real integer double precision
dot_product (vector_a, vector_b)			
dprod (x, y)			
eoshift (array, shift, boundary, dim)	boundary, dim		
epsilon (x)			
erf(x)			
erfc(x)			
exp (x)			
exponent (x)			
floor (a, kind)	kind		
fraction (x)			
get_command(command, length, status)	command length, status		
get_command_argument(number, value, length, status)	value, length, status		
get_environment_variable(name, value, length, status, trim_name)	value, length, status, trim_name		
huge (x)			
iachar (c)			
iand (i, j)			
ibclr (i, pos)			
ibits (i, pos, len)			
ibset (i, pos)			
ichar (c)			
ieor (i, j)			

index (string, substring, back)	back	index (string, substring)	character default character
generic procedure	optional arguments	specific name	specific argument type
int (a, kind)	kind		
ior (i, j)			
ishft (i, shift)			
ishftc (i, shift, size)	size		
is_iostat_end()			
is_iostat_eor()			
kind (x)			
lbound (array, dim)	dim		
len (string)		len (string)	character
len_trim (string)			
lge (string_a, string_b)			
lgt (string_a, string_b)			
lle (string_a, string_b)			
llt (string_a, string_b)			
log (x)		alog (x) clog (x) dlog (x)	real complex double precision
log10 (x)		alog10 (x) dlog10 (x)	real double precision
logical (l, kind)	kind		
matmul (matrix_a, matrix_b)			
max (a1, a2, a3, ...)	a3, ...	max0 (a1,a2,...) amax1 (a1,a2,...) dmax1 (a1,a2,...)	integer real double precision
maxexponent (x)			
maxloc (array, dim, mask)	dim, mask		
maxval (array, dim, mask)	dim, mask		
merge (tsource, fsource, mask)			
min (a1, a2, a3, ...)	a3, ...	min0 (a1,a2,...) amin1 (a1,a2,...) dmin1 (a1,a2,...)	integer real double precision
minexponent (x)			
minloc (array, dim, mask)	dim, mask		
minval (array, dim, mask)	dim, mask		
mod (a, p)		mod (a, p) amod (a, p) dmod (a, p)	integer real double precision
modulo (a, p)			
mvbits (from, frompos, len, to, topos)			
nearest (x, s)			
new_line(a)			character
nint (a, kind)	kind	nint (a) idnint (a)	real double precision
null (mold)	mold		
pack (array, mask, vector)	vector

sum (array, dim, mask) system_clock (count, count_rate, count_max)	dim, mask count, count_rate, count_max		
tan (x)		tan (x) dtan (x)	real double precision
tanh (x)		tanh (x) dtanh (x)	real double precision
tiny (x) transfer (source, mold, size) transpose (matrix) trim (string) ubound (array, dim) unpack (vector, mask, field) verify (string, set, back)	size dim back		

INTRINSIC PROCEDURE DETAILS

The intrinsic procedures are described in detail in this section. A “pseudo” interface block, without the **interface ... end interface** bracketing keywords, describes the interface of each procedure; the semantics is described in comments in the interface, often augmented by text following the interface. Constraints and other relevant information are also included, either in the interface comments or in the following text.

Most of the intrinsic procedures are generic over the various kinds of the argument type - for example, **sqrt** is generic for single, double precision, and quad precision real

arguments. Unless explicitly mentioned otherwise, each single-argument intrinsic procedure is generic in this sense, with the result kind being the same as the argument kind. Similarly, each intrinsic function with one argument plus a **kind** argument is generic in this sense, but with the result kind as specified by the **kind** argument.

Intrinsic procedures may be classified as either elemental or transformational (most are elemental). If an intrinsic procedure is elemental the interface starts with the keyword **elemental**; otherwise that procedure is transformational. (In a call to an elemental function with two or more arguments, the actual arguments must be conformable; but note that a scalar is conformable with any array.) Similarly, some intrinsic functions are identified as inquiry functions with the keyword **inquiry**; actual arguments to inquiry functions need not be defined.

All intrinsic function arguments are **intent(in)** and so the intent for these arguments is not explicitly given in the interface; however, the argument intent is explicitly specified for each argument of the five intrinsic subroutines. The argument names can be used as actual argument keywords.

Many of the intrinsic procedures take array arguments of any rank. These arguments are shown as rank one (**:**) in the following interfaces, and the descriptions identify which arguments may be generic over rank and the resulting meaning of the different ranks.

```
abs (a)
  elemental function abs(a)      ! the |a|
    real :: abs                  ! or integer if a is of type integer
    real :: a                    ! or type integer or type complex
  end function
```

If **a** is complex with value (x,y), **abs** returns an approximation to $\sqrt{a^{**2}+b^{**2}}$.

```
achar (i)
  elemental function achar(i) ! the ith ascii character
    character :: achar        ! the result kind is kind('a')
    integer :: i
  end function
```

Note that `achar(iachar(x))` is **x** for any character **x** of default kind represented by the processor.

```
acos (x)
  elemental function acos(x) ! the arccosine (inverse cosine)
    real :: acos
    real :: x                ! |x| ≤ 1 or of type complex
  end function
```

The result has a value equal to a processor-dependent approximation to $\arccos(x)$, expressed in radians. It lies in the range $0 \leq \text{acos}(x) \leq \text{pi}$. If complex, the real portion lies in the range $0 \leq \text{acos}(x) \leq \text{pi}$.

```

adjustl (string)
  elemental function adjustl(string)      ! remove leading blanks
    character(len(string)) :: adjustl    ! (the same number of trailing
                                         ! blanks added)

    character(*) :: string
  end function

adjustr (string)
  elemental function adjustr(string)      ! remove trailing blanks
    character(len(string)) :: adjustr    ! (the same number of leading
                                         ! blanks added)

    character(*) :: string
  end function

aimag (z)
  elemental function aimag(z) ! imaginary part of z
    real :: aimag             ! if z = (x, y), aimag is y
    complex :: z
  end function

aint (a, kind)
  elemental function aint(a,kind)      ! truncate a
    real(kind) :: aint                 ! if kind is absent the result kind
                                         ! is kind(a)

    real :: a                          ! may be any kind
    integer, optional :: kind          ! if present, must be a scalar
                                         ! initialization expression

  end function

```

If $|a| < 1$, `aint (a)` has the value 0; if $a > 1$, `aint (a)` has the sign of `a` and a value equal to the integer whose magnitude is the largest integer that does not exceed the magnitude of `a`.

```

all (mask, dim)
  function all(mask,dim)                ! returns true if all of mask (along dim)
                                         ! is true

    logical :: all                      ! all is an array if dim is present and
                                         ! mask rank > 1

    logical :: mask(:)                  ! may be any kind, any rank
    integer, optional :: dim            ! if present, 1≤dim≤n, where n is rank of
                                         ! mask

  end function

```

The result is scalar if `dim` is absent or `mask` has rank one; otherwise, the result is an array of rank `n-1` and of shape `(d1,d2,...,ddim 1,ddim+1,...,dn)` where `(d1,d2,...,dn)` is the shape of `mask`.

```

allocated (array)
  inquiry function allocated(array)      ! check allocation status of
                                         ! argument

    logical :: allocated                 ! true if array is currently
                                         ! allocated; false otherwise

    real :: array(:)                   ! array can be any type and any rank

  end function

```

The actual argument for **array** must be an allocatable array with defined allocation status.

```
anint (a, kind)
  elemental function anint(a,kind)    ! integer value nearest a
  real(kind) :: anint                  ! if kind is absent the result kind
                                      ! is kind(a)

  real :: a
  integer, optional :: kind            ! if present, must be a scalar
                                      ! initialization expression

end function
```

If $a > 0$ **anint(a)** is **aint (a + 0.5)**; if $a \leq 0$ **anint (a)** is **aint (a - 0.5)**.

```
any (mask, dim)
  function any(mask,dim)              ! returns true if any of mask (along dim)
                                      ! is true
  logical :: any                      ! any is an array if dim is present and
                                      ! mask rank > 1
  logical :: mask(:)                 ! may be any kind, any rank
  integer, optional :: dim            ! if present,  $1 \leq \text{dim} \leq n$ , where  $n$  is rank of
                                      ! mask

end function
```

The result is scalar if **dim** is absent or **mask** has rank one; otherwise, the result is an array of rank $n-1$ and of shape $(d_1, d_2, \dots, d_{\text{dim}-1}, d_{\text{dim}+1}, \dots, d_n)$ where (d_1, d_2, \dots, d_n) is the shape of **mask**.

```
asin (x)
  elemental function asin(x)          ! the arcsine (inverse sine)
  real :: asin
  real :: x                          !  $x \leq 1$  or of type complex

end function
```

The result has a value equal to a processor-dependent approximation to $\arcsin(x)$, expressed in radians. It lies in the range $-\pi/2 \leq \text{asin}(x) \leq \pi/2$. If complex, the real portion lies in the range $-\pi/2 \leq \text{asin}(x) \leq \pi/2$.

```
associated (pointer, target)
  inquiry function associated(pointer,target)    ! check association
                                                  ! status of argument
  logical :: associated                        ! true if pointer is
                                                  ! currently associated,
                                                  ! else false
  real, pointer :: pointer(:)                 ! pointer can be any
                                                  ! type, any rank
  real, optional :: target(:)                 ! target can be any
                                                  ! type, any rank

end function
```

The actual argument for **pointer** must be a pointer with defined pointer association status. The actual argument for **target**, if present, must be either a target or a pointer with defined pointer association status. If **target** is absent, the result is true if **pointer** is currently associated with a target and false otherwise. If **target** is present and is a target,

the result is true if **pointer** is currently associated with **target** and false if it is not. If **target** is present and is a pointer, the result is true if both **pointer** and **target** are currently associated with the same target, and false otherwise.

```
atan (x)
  elemental function atan(x) ! the arctangent (inverse tangent)
    real :: atan
    real :: x                ! may be complex
  end function
```

The result has a value equal to a processor-dependent approximation to $\arctan(x)$, expressed in radians, that lies in the range $-\pi/2 \leq \text{atan}(x) \leq \pi/2$.

```
atan2 (y, x)
  elemental function atan2(x) ! the arctangent (inverse tangent)
    real :: atan2            ! of the nonzero complex number (x, y)
    real :: y
    real :: x
  end function
```

The result has a value equal to a processor-dependent approximation to the $\arctan(y/x)$, expressed in radians that lies in the range $-\pi \leq \text{atan2}(y,x) \leq \pi$. If $y > 0$, the result is positive. If $y = 0$, the result is zero if $x > 0$ and π if $x < 0$. If $y < 0$, the result is negative. If $x = 0$, the absolute value of the result is $\pi/2$.

```
bit_size (i)
  inquiry function bit_size(i) ! number of bits in argument i
    integer :: bit_size
    integer :: i                ! i may be an array of any rank
  end function
```

```
btest (i, pos)
  elemental function btest(i,pos) ! returns true if the bit in
    ! position pos of i is 1
    logical :: btest
    integer :: i
    integer :: pos              ! 0 ≤ pos < bit_size(i)
  end function
```

```
ceiling (a)
  elemental function ceiling(a) ! least integer greater than or
    ! equal to a
    integer :: ceiling
    real :: a
  end function
```

```
char (i, kind)
  elemental function char(i,kind) ! character in the ith position of
    ! the character set
    character(kind) :: char      ! default character kind if kind is
    ! absent
    integer :: i                 ! in range 0 ≤ i ≤ n-1 where n is #
    ! of characters
    integer, optional :: kind    ! if present, must be a scalar
    ! initialization expression
```

```
end function
```

Note that $\text{ichar}(\text{char}(y, \text{kind}(x))) = y$ and $\text{char}(\text{ichar}(x), \text{kind}(x)) = x$.

```
cmplx (x, y, kind)  
  elemental function cmplx(x,y,kind)      ! complex number with real  
                                             ! part x, imaginary part y  
  complex(kind) :: cmplx                  ! or default kind if kind is  
                                             ! absent  
  real :: x                                ! or integer or complex  
  real, optional :: y                     ! or integer, or absent if x  
                                             ! is complex  
  integer, optional :: kind               ! if present, must be a scalar  
                                             ! initialization expression  
end function
```

If **y** is absent and **x** is not complex, then the imaginary part of the result is zero.

```
command_argument_count ()  
  integer function command_argument_count ()      ! the number of command  
                                                    ! line arguments  
end function
```

```
conjg (z)  
  elemental function conjg(z) ! the conjugate of a complex number  
  complex :: conjg  
  complex :: z  
end function
```

```
cos (x)  
  elemental function cos(x)      ! the cosine of x  
  real :: cos                     ! same type and kind as x  
  real :: x                       ! may be complex  
end function
```

If **x** is of type real, it is regarded as a value in radians; if **x** is of type complex, its real part is regarded as a value in radians.

```
cosh (x)  
  elemental function cosh(x)      ! the hyperbolic cosine of x  
  real :: cosh  
  real :: x                       ! may be complex  
end function
```

```
count (mask, dim)  
  function count(mask,dim)      ! count the number of true elements of  
                                ! mask  
  integer :: count              ! count is an array if dim is present and  
                                ! mask rank > 1  
  logical :: mask(:)            ! may be any kind, any rank  
  integer, optional :: dim      ! if present,  $1 \leq \text{dim} \leq n$ , where  $n$  is rank  
                                ! of mask  
end function
```

If **dim** is present and *n* is greater than 1 then the result is an array of rank *n*-1. For example, if **mask** is a 3x2 array and **dim** is 2, then the result is a one-dimensional array of size 3, with the count taking place along each row of **mask**.

```

cpu_time (time)
  subroutine cpu_time (time)      ! return cpu usage time
    real :: time                  ! processor dependent approximation
                                ! in seconds
  end subroutine

cshift (array, shift, dim)
  function cshift(array,shift,dim) ! circularly shift array
    real :: cshift(:)              ! same type, kind, and shape as
                                ! array
    real :: array(:)              ! or any type, kind, and rank (not
                                ! scalar)
    integer :: shift               ! amount to be shifted, positive for
                                ! left shifts
    integer, optional :: dim       ! if present,  $1 \leq \text{dim} \leq n$ , where n is
                                ! rank of array
  end function

```

Positive **shift** amounts are “left” shifts (e.g., `cshift(i)=array(i+1)`) and negative shifts are “right”; values shifted “off” one end are routed into the other end. If **dim** is absent it is assumed to be 1. If **array** has rank greater than 1 then *n*-1 “one-dimensional shifts” take place along the dimension specified by **dim**. For example, if **array** is a 3x2 array and **dim**=1, each of the two columns of **array** are shifted an amount specified by **shift**. **shift** is allowed to be an array of rank *n*-1, specifying a different shift amount for each “one dimensional shift”. In the preceding example, **shift** could be a one-dimensional array of two elements, having values, say, of 2 and -1; in this case the first column of the array will be circularly shifted “up” two and the second column will be shifted “down” one.

```

date_and_time (date, time, zone, values)
  subroutine date_and_time(date,time,zone,values)      ! returns date and
                                                        ! time information
    character(*), optional, intent(out) :: date       ! date in CCYYMODD
                                                        ! format
    character(*), optional, intent(out) :: time       ! time in
                                                        ! HHMMSS.SSS
                                                        ! format
    character(*), optional, intent(out) :: zone       ! zone in ±HHMM
                                                        ! format
    integer, optional, intent(out) :: values(:)       ! date, time, and
                                                        ! zone in integer
                                                        ! form
  end subroutine

```

Returned results are compatible with the representations defined in ISO 8601:1988. CC is the century, YY the year of the century, MO the month, DD the day of the month, HH the hour of the day, MM the minutes of the hour, and SS.SSS the seconds/milliseconds. For **zone**, the result is the hours and minutes from Coordinated Universal Time. For **values**, **values(1)** is the integer form of CCYY - e.g., the year, **values(2)** is MO, **values(3)** is DD,

values(4) is the zone, **values(5)** is **HH** (range 0:23), **values(6)** is **MM** (range 0:59), **values(7)** is the seconds (range 0:60), and **values(8)** is the milliseconds.

```
double (a)
  elemental function dble(a)      ! converts a to a double precision real
                                ! value
                                ! where DOUBLE is the double-precision
                                ! kind value or integer or complex,
                                ! of any kind
    real(DOUBLE) :: dble
  end function
```

If **a** is complex, then **dble** returns the real part of **a** in double precision form.

```
digits (x)
  inquiry function digits(x)      ! returns the model value of n if x is
                                ! integer, or q if x is real
    integer :: digits
    integer :: x                  ! may also be real and/or an array
  end function
```

```
dim (x, y)
  elemental function dim(x,y)     ! returns max(0,x-y)
    integer :: din                ! same type and kind as x (and y)
    integer :: x, y               ! may also be real; y must have same type
                                ! and kind as x
  end function
```

```
dot_product (vector_a, vector_b)
  function dot_product(vector_a,vector_b) ! the dot-product
                                          ! multiplication of numeric or
                                          ! logical vectors
    real :: dot_product              ! may also be logical or
                                          ! integer - see discussion
    real :: vector_a(:), vector_b(:) ! one-dimensional arrays of
                                          ! the same size and both
                                          ! either of type logical or of
                                          ! any numeric type
  end function
```

If the vectors are size zero, the result value is either zero or false; otherwise, if the vectors are of type logical the result is type logical with value and kind of **any(vector_a.and.vector_b)**, if **vector_a** is of type integer or real the result value and kind are those of **sum(vector_a*vector_b)**, and else the result value and kind are those of **sum(conjg(vector_a)*vector_b)**.

```
dprod (x, y)
  elemental function dprod(x,y)     ! returns double-precision product
                                ! of two default real values
    real(DOUBLE) :: dprod           ! where DOUBLE is the double-
                                ! precision kind value
    real :: x, y
  end function
```

```

eoshift (array, shift, boundary, dim)
  function eoshift(array,shift,boundary,dim)      ! end-off shift off
                                                    ! array
                                                    ! same type, kind, and
                                                    ! shape as array
                                                    ! or any type, kind, and
                                                    ! rank (not scalar)
                                                    ! amount to be shifted,
                                                    ! positive for left
                                                    ! shifts
                                                    ! same type and kind as
                                                    ! array - value for
                                                    ! vacated positions
                                                    ! if present,  $1 \leq \text{dim} \leq n$ ,
                                                    ! where n is rank of
                                                    ! array

    real :: eoshift(:)

    real :: array(:)

    integer :: shift

    integer, optional :: boundary

    integer, optional :: dim

  end function

```

eoshift is exactly the same as **cshift**, except that values shifted “off” one end are not routed into the vacated positions on the other end; the **boundary** value is placed in the vacated positions. If **boundary** is omitted, the default value is 0, 0.0, (0.0,0.0), false, or blanks, depending on whether **array** is type integer, real, complex, logical, or character, respectively. **boundary** is allowed to be an array of rank n-1, specifying a different fill value amount for each vacated position.

```

epsilon (x)
  inquiry function epsilon(x) ! a positive value almost negligible
  compared to unity
    real :: epsilon          ! same type and kind as x
    real :: x                ! may be any kind; may be an array of any
                              ! rank

  end function

```

```

erf (x)
  elemental function erf(x) ! the error function
    real :: erf             ! type and kind of x, must be real
    real :: x

  end function

```

```

erfc (x)
  elemental function erfc(x) ! the complementary error function
    real :: erfc            ! type and kind of x, must be real
    real :: x

  end function

```

```

exp (x)
  elemental function exp(x) ! an approximation to  $e^{*x}$ 
    real :: exp             ! type and kind of x may be complex, in
    real :: x               ! which case its imaginary part is
                              ! regarded as a value in radians

  end function

```

```

exponent (x)
  elemental function exponent(x) ! the real model exponent part of x
    integer :: exponent
    real :: x

```

```
end function

floor (a)
  elemental function floor(a) ! greatest integer less than or equal to a
    integer :: floor
    real :: a
  end function

fraction (x)
  elemental function fraction(x) ! the real model fractional part of x
    real :: fraction
    real :: x
  end function

get_command (command, length, status)
  subroutine get_command (command, length, status)
    character(len=*), optional :: command ! the command line
    integer, optional :: length           ! default integer kind
    integer, optional :: status           ! default integer kind
  end subroutine
```

`length` returns the actual length of the command line. If `command` is present and `len(command) < length`, `status` is set to -1, otherwise it is set to 0.

```
get_command_argument (number, value, length, status)
  subroutine get_command_argument (number, value, length, status)
    integer :: number           ! default integer kind
    character(len=*), optional :: value ! command line argument
    integer, optional :: length ! default integer kind
    integer, optional :: status ! default integer kind
  end subroutine
```

If `number` is 0, the name of the program is returned in `command`. `length` returns the actual length of the command line argument. If `value` is present and `len(value) < length`, `status` is set to -1, if `number` is greater than the number of command line arguments, `status` is set to 1, otherwise it is set to 0.

```
get_environment_variable (name, value, length, status, trim_name)
  subroutine get_environment_variable (name, value, length, status, &
                                     trim_name)
    character(len=*) name           ! environment variable name
    character(len=*), optional :: value ! environment variable value
    integer, optional :: length      ! default integer kind
    integer, optional :: status      ! default integer kind
    integer, optional :: trim_name   ! default logical kind
  end subroutine
```

`length` returns the actual length of the environment variable. If `value` is present and `len(value) < length`, `status` is set to -1, otherwise it is set to 0. If `name` does not exist, `status` is set to 1.

```
huge (x)
  inquiry function huge(x) ! the largest value for the type and kind
                          ! of x
```

```

    real :: huge                ! same type and kind as x
    real :: x                  ! may be any kind; may be integer; may be
                                ! an array
end function

iachar (c)
  elemental function iachar(c)  ! same as ichar, except the ASCII
                                ! collating sequence (ISO 646:1983)
                                ! is used instead of the processor's
    integer :: iachar
    character :: c
end function

iand (i, j)
  elemental function iand(i,j) ! perform logical and on bits of i and j
    integer :: iand             ! same kind as i (and j)
    integer :: i, j             ! any kind, but both must be the same kind
end function

```

The result is the bit-by-corresponding-bit *and* of the arguments; if both argument bits are 1 the corresponding result bit is 1, otherwise the result bit is 0.

```

ibclr (i, pos)
  elemental function ibclr(i,pos)
    integer :: ibclr            ! same as i, but with the specified bit
                                ! set to 0
    integer :: i                ! may be any kind
    integer :: pos              ! position of bit in i to set to zero;
                                ! 0≤pos<bit_size(i)
end function

ibits (i, pos, len)
  elemental function ibits(i,pos,len) ! "extract" a string of bits
                                        ! from i
    integer :: ibits            ! same type and kind as i
    integer :: i                ! may be any kind
    integer :: pos              ! position of first bit to
                                ! extract; pos≥0
    integer :: len              ! number of bits to extract;
                                ! len≥0 and pos+len < bit_size(i)
end function

```

The result has the sequence of **len** bits from **i**, beginning at bit **pos**; these bits are in the rightmost bit positions of the result, with all other bits zero.

```

ibset (i, pos)
  elemental function ibset(i,pos)    ! same as ibclr, except the
                                      ! specified bit is set to 1 instead
                                      ! of 0
    integer :: ibset
    integer :: i
    integer :: pos
end function

ichar (c)
  elemental function ichar(c) ! position of a character in the processor
                                ! collating sequence

```

```
integer :: ichar
character :: c
end function                                ! same as iachar if the processor
                                           ! collating sequence is ASCII

ieor (i, j)
  elemental function ieor(i,j) ! perform logical exclusive-or on bits of
                                ! i and j
                                ! same kind as i (and j)
    integer :: ieor            ! any kind, but both must be the same kind
    integer :: i, j
  end function
```

The result is the bit-by-corresponding-bit *exclusive-or* of the arguments; if one of the argument bits is 1 and the other is 0, the corresponding result bit is 1, otherwise the result bit is 0.

```
index (string, substring, back)
  elemental function index(string,substring,back) ! search string for a
                                                    ! a substring of
                                                    ! substring
                                                    ! beginning position
                                                    ! of substring in
                                                    ! string (or zero)
                                                    ! may be any kind
    character(*) :: string                        ! same kind as string
    character(*) :: substring                    ! if present and
    logical, optional :: back                   ! true, search is
                                                    ! from back of string

  end function
```

If **back** is absent or present with the value false, the result is the minimum positive value of **i** such that **string(i:i+len(substring)-1) == substring** or zero if there is no such value; if **back** is present with the value true, the result is the maximum value of **i** less than or equal to **len(string)-len(substring)+1** such that **string(i:i+len(substring)-1) == substring** or zero if there is no such value. Zero is returned if **len(string) < len(substring)** and one is returned if **len(substring) == 0**.

```
int (a, kind)
  elemental function int(a,kind) ! convert a to an integer value (of
                                ! specified kind)
                                ! the converted integer value
    integer(kind) :: int        ! may be any numeric type
    real :: a                  ! if present, must be a scalar
    integer, optional :: kind  ! initialization expression. if kind
                                ! is absent, the result kind is
                                ! default integer

  end function
```

If **a** is of type integer, the result is this same value, but possibly of a different kind. If **a** is of type real, the real value is truncated toward zero (e.g., **int(3.7)** is 3 and **int(-3.7)** is -3). If **a** is of type complex, the result is **int(real(a))**.

```

ior (i, j)
  elemental function ior(i,j) ! perform logical inclusive-or on bits of
                                ! i and j
    integer :: ior             ! same kind as i (and j)
    integer :: i, j            ! any kind, but both must be the same kind
  end function

```

The result is the bit-by-corresponding-bit *inclusive-or* of the arguments; if either one, or both, of the argument bits is 1, the corresponding result bit is 1, otherwise the result bit is 0.

```

ishft (i, shift)
  elemental function ishft(i,shift) ! logically end-off shift the
                                      ! bits of i the amount shift
    integer :: ishft                ! same kind as i
    integer :: i                    ! may be any kind
    integer :: shift                ! amount to shift the bit
                                      ! pattern of i; shift must
                                      ! have a magnitude less than
                                      ! or equal to bit_size(i)
  end function

```

The result is the value obtained by shifting the bits of **i** by **shift** positions. If **shift** is positive, the shift is to the left. Bits shifted out are lost; zeros are shifted in at the opposite end.

```

ishftc (i, shift, size)
  elemental function ishft(i,shift, size) ! same as ishft, but the
                                           ! shift is circular
                                           ! rather than end-off
    integer :: ishft                ! same kind as i
    integer :: i                    ! may be any kind
    integer :: shift                ! amount to shift the
                                           ! bit pattern of i;
                                           ! shift ≤ size
    integer, optional :: size       ! 0 ≤ size < bit_size(i)
    end function                    ! if size is omitted,
                                           ! bit_size(i) is assumed

```

The result has the value obtained by shifting the bits of **i** by **shift** positions. If **shift** is positive, the shift is to the left. Bits shifted out are shifted into at vacated positions at the opposite end.

```

is_eof (i)
  logical function is_eof(i) ! returns .true. if i equals the value
                              ! returned in an IOSTAT specifier for end
                              ! of file
    integer :: i              ! default integer kind
  end function

```

```
is_eor (i)
  logical function is_eor(i)    ! returns .true. if i equals the value
                                ! returned in an IOSTAT specifier for end
                                ! of record
    integer :: i                ! default integer kind
  end function

kind (x)
  inquiry function kind(x)      ! the kind type parameter value of any
                                ! object
    integer :: kind             ! the kind value of x
    real :: x                   ! may be any intrinsic type and any kind;
                                ! may be an array
  end function

lbound (array, dim)
  inquiry function lbound(array,dim) ! the lower bound(s) of array
    integer :: lbound           ! scalar if dim is present; a rank
                                ! one array otherwise
    real :: array(:)            ! may have any type, kind, and
                                ! rank
    integer, optional :: dim     ! if present,  $1 \leq \text{dim} \leq n$ , where  $n$ 
                                ! is the rank of array
  end function

If dim is present the result is a scalar and is the lower bound of array along the
dimension dim. If dim is absent the result is a one-dimensional array whose size is the
rank of array, and the value of each element of the result is the lower bound of that
dimension of array. If array is an array expression other than an array name (e.g., an
array section), the lower bound for each dimension is 1.

len (string)
  inquiry function len(string)    ! the length (numbers of characters)
                                ! of a string
    integer :: len                ! the length of string
    character(*) :: string        ! may be any kind; may be an array
  end function                    ! if string is an array, len is the
                                ! length of each element

len_trim (string)
  elemental function len_trim(string) ! same as len(trim(string))
    integer :: len_trim            ! the length of string with all
                                ! trailing blanks removed
    character(*) :: string
  end function

lge (string_a, string_b)
  elemental function lge(string_a,string_b) ! string comparison, based
                                ! on ASCII
    logical :: lge                 ! true if string_a >=
                                ! string_b in the ASCII
                                ! collating sequence,
                                ! false otherwise
    character(*) :: string_a, string_b
  end function
```

```

lgt (string_a, string_b)
  elemental function lgt(string_a,string_b) ! string comparison, based
                                           ! on ASCII
  logical :: lgt                          ! true if string_a >
                                           ! string_b in the ASCII
                                           ! collating sequence,
                                           ! false otherwise
  character(*) :: string_a, string_b
end function

lle (string_a, string_b)
  elemental function lle(string_a,string_b) ! string comparison, based
                                           ! on ASCII
  logical :: lle                          ! true if string_a <=
                                           ! string_b in the ASCII
                                           ! collating sequence,
                                           ! false otherwise
  character(*) :: string_a, string_b
end function

llt (string_a, string_b)
  elemental function llt(string_a,string_b) ! string comparison, based
                                           ! on ASCII
  logical :: llt                          ! true if string_a <
                                           ! string_b in the ASCII
                                           ! collating sequence,
                                           ! false otherwise
  character(*) :: string_a, string_b
end function

log (x)
  elemental function log(x)               ! the natural logarithm, logex
  real :: log                             ! same type and kind as x
  real :: x                               ! may be complex; if real, x > 0
  end function                            ! if complex, x must not be zero

log10 (x)
  elemental function log10(x)             ! base-10 logarithm, log10x
  real :: log10                           ! same kind as x
  real :: x                               ! x > 0
  end function

logical (l, kind)
  elemental function logical(l,kind)      ! convert between logical kinds
  logical(kind) :: logical                ! the value of l, but with kind
                                           ! kind
  logical :: l                            ! may be any kind
  integer, optional :: kind               ! if present, must be a scalar
                                           ! initialization expression
  end function                            ! if kind is absent, the result
                                           ! kind is default logical

```

```
matmul (matrix_a, matrix_b)
  function matmul(matrix_a,matrix_b)      ! matrix multiplication of two
                                           ! numeric or logical matrices
                                           ! type and kind determined by
                                           ! the arguments - see below
  real :: matmul(:, :)                   ! may be any kind; may be
                                           ! integer, complex or logical;
                                           ! one of the argument matrices
                                           ! (but not both) may be rank
                                           ! one
end function
```

The two arguments must be both of type logical or of numeric (integer, real, complex) type. The size of the first (or only) dimension of **matrix_b** must equal the size of the last (or only) dimension of **matrix_a**. There are three cases: (1) **matrix_a** has shape (n,k) and **matrix_b** has shape (k,m), in which case the result has shape (n,m); (2) **matrix_a** has shape (k) and **matrix_b** has shape (k,m), in which case the result has shape (m); (3) **matrix_a** has shape (n,k) and **matrix_b** has shape (k), in which case the result has shape (n). For case (1) the (i,j) element of the result has the value and kind of **sum(matrix_a(i,:)*matrix_b(:,j))** if the arguments are of numeric type and **any(matrix_a(i,:).and.matrix_b(:,j))** otherwise. For case (2) the (i) element of the result has the value and kind of **sum(matrix_a(:)*matrix_b(:,i))** if the arguments are of numeric type and **any(matrix_a(:).and.matrix_b(:,i))** otherwise, and for case (3) the (i) element of the result has the value and kind of **sum(matrix_a(i,:)*matrix_b(:))** if the arguments are of numeric type and **any(matrix_a(i,:).and.matrix_b(:))** otherwise.

```
max (a1, a2, a3, ...)
  elemental function max(a1,a2,a3,...)    ! return the maximum of the
                                           ! argument values
  real :: max                             ! same type and kind as the
                                           ! arguments
  real :: a1, a2                          ! may be integer, but all
  real, optional :: a3, ...               ! arguments must have the same
                                           ! type and kind
end function

maxexponent (x)
  inquiry function maxexponent(x)         ! maximum model exponent that this
                                           ! kind of real can have
  integer :: maxexponent
  real :: x                               ! may be any kind; may be an array
end function
```

```

maxloc (array, mask)
  function maxloc(array,mask)
                                ! location in array of
                                ! element with the maximum
                                ! value
                                ! result element values are
                                ! the subscripts of the
                                ! location
                                ! any kind, any rank; can
                                ! be type integer
                                ! must be same shape as
                                ! array
    integer :: maxloc(:)
    real :: array(:)
    logical, optional :: mask(size(array))
  end function

```

The size of the result is equal to the rank of **array**. The value of the *k*th element of the result is the value of the *k*th subscript of the location of the element with the maximum value. If more than one element of **array** has this maximum value, the location of the first, in array element order, is returned. If **mask** is present, only those locations in **array** corresponding to the true values in **mask** are searched for the maximum value.

```

maxval (array, dim, mask)
  function maxval(array,dim,mask)
                                ! the maximum value in
                                ! array, or along one of its
                                ! dimensions
                                ! same kind and type as
                                ! array
                                ! any kind, any rank; can be
                                ! type integer
                                ! dimension along which to
                                ! determine maximum values
                                ! must be same shape as
                                ! array
    real :: maxval
    real :: array(:)
    integer, optional :: dim
    logical, optional :: mask(size(array))
  end function

```

The result is scalar if **dim** is omitted or **array** has rank 1 (as illustrated in the interface), in which case the value returned is the maximum element value in **array**. If **array** has rank *n* greater than 1 and **dim** is present, $1 \leq \text{dim} \leq n$ and **dim** specifies the dimension along which to determine the maximum values; in this case the result is an array of rank *n*-1 and shape (d1,d2,...,ddim-1, ddim+1,...,dn) where (d1,d2,...,dn) is the shape of **array** and each value of the result is the maximum value along the **dim** dimension of **array**. If **mask** is present only those elements of **array** corresponding to the true values in **mask** are searched for the maximum value.

```
merge (tsource, fsource, mask)
  elemental function merge(tsource,fsource,mask) ! select one of two
                                                    ! arguments, based on a
                                                    ! mask
  real :: merge                                     ! same type and kind as
                                                    ! tsource
  real :: tsource                                  ! may be of any type
                                                    ! and kind
  real :: fsource                                  ! same type and kind as
                                                    ! tsource
  logical :: mask                                  ! return tsource if
                                                    ! mask is true,
  end function                                     ! fsource if mask is
                                                    ! false
```

merge is an elemental function and is most often used to merge two arrays, based on the (conformable) **mask**.

```
min (a1, a2, a3, ...)
  elemental function min(a1,a2,a3,...) ! return the minimum of the
                                        ! argument values
  real :: min                          ! same type and kind as the
                                        ! arguments
  real :: a1, a2                      ! may be integer,
  real, optional :: a3, ...           ! but all arguments must have
                                        ! the same type and kind
  end function
```

```
minexponent (x)
  inquiry function minexponent(x) ! minimum model exponent that this
                                   ! kind of real can have
  integer :: minexponent
  real :: x                       ! may be any kind; may be an array
  end function
```

```
minloc (array, mask)
  function minloc(array,mask) ! same as maxloc,
  integer :: minloc(:)        ! but with minimum value rather than
                               ! maximum value
  real :: array(:)
  logical, optional :: mask(size(array))
  end function
```

```
minval (array, dim, mask)
  function minval(array,dim,mask) ! same as maxval,
  real :: minval                  ! but with minimum value rather than
                                   ! maximum value
  real :: array(:)
  integer, optional :: dim
  logical, optional :: mask(size(array))
  end function
```

```

mod (a, p)
  elemental function mod(a,p)      ! the remainder function (has sign of a)
    integer :: mod                  ! same type and kind as a; value is
                                   ! a-int(a/p)*p
    integer :: a                    ! any kind; may be real
    integer :: p                    ! same type and kind as a; the value of
                                   ! p must not be zero
  end function                      ! mod and modulo are the same for
                                   ! positive values of a and p

```

```

modulo (a, p)
  elemental function modulo(a,p)    ! the modulo function (has sign of p)
    integer :: modulo               ! same type and kind as a; value is
                                   ! a-floor(a/p)*p
    integer :: a                    ! any kind; may be real
    integer :: p                    ! same type and kind as a; the value
                                   ! of p must not be zero
  end function                      ! mod and modulo are the same for
                                   ! positive values of a and p

```

```

move_alloc (from, to)
  pure subroutine move_alloc(from,to) ! move an allocation
    any, allocatable() :: from       ! any kind
    any, allocatable() :: to         ! any kind
  end function

```

from may be any kind and rank, but must be allocatable. **to** must be the same kind and rank and must be allocatable.

```

mvbits (from, frompos, len, to, topos)
  elemental subroutine mvbits(from,frompos,len,to,topos) ! move bits
                                   ! from from to to
    integer, intent(in) :: from     ! may be any kind
    integer, intent(in) :: frompos   ! 0 ≤ frompos < bit_size(from)
    integer, intent(in) :: len       ! 0 ≤ len
    integer, intent(inout) :: to     ! same kind as from (and may be the
                                   ! same object)
    integer, intent(in) :: topos     ! 0 ≤ topos; (topos+len) <
                                   ! bitsize(to)
  end subroutine

```

Copies **len** bits from object **from**, starting at bit position **frompos** in **from**, to object **to**, starting at bit position **topos** in **to**.

```

nearest (x, s)
  elemental function nearest(x,s)    ! the nearest value in the specified
    real :: nearest                  ! direction
    real :: x                        ! same kind as x; value is that
    real :: s                        ! nearest x, but not x
                                   ! may be any kind
                                   ! must not be zero; s > 0 means
                                   ! nearest > x
                                   ! s < 0 means nearest < x
  end function

```

```
new_line (a)
character(len=1) function new_line(a)      ! new line character
  character :: a                          ! scalar or array
end function
```

This function returns char(10).

```
nint (a, kind)
elemental function nint(a,kind)            ! integer nearest to a
  integer(kind) :: nint                    ! value is int(a-sign(0.5,a))
  real :: a
  integer, optional :: kind               ! if present, must be a scalar
                                           ! initialization expression
end function                             ! if kind is absent, the result kind is
                                           ! default integer
```

```
not (i)
elemental function not(i)                  ! logical bit-wise complement
  integer :: not                          ! the bit complement of i
  integer :: i
end function                             ! 1 bits in i become 0 in not; 0 bits in i
                                           ! become 1 in not
```

```
null (mold)
function null(mold)                       ! disassociated pointer
  any :: null                             ! type determined by mold or context, see
                                           ! below
  any :: mold
end function
```

mold is a pointer of any type. Its association status can be undefined, disassociated, or associated. If its status is associated, the target does not have to be defined. If *mold* is present the result type is the same as *mold*; otherwise the result type is determined by the context

```
pack (array, mask, vector)
function pack(array,mask,vector)           ! pack an array of any shape into an
                                           ! array of rank 1
  real :: pack(:)                         ! same type and kind as array
  real :: array(:)                       ! maybe any type, kind, and shape
  logical :: mask(size(array))           ! same shape as array
  real, optional :: vector(:)            ! if present, must have at least
                                           ! count(mask) elements
end function
```

If **vector** is present the size of **pack** is the size of **vector**; otherwise the size of **pack** is **count(mask)**. The elements of **array** that correspond to true values in **mask** are placed in **pack**, starting with the first element of **pack** and in array element order from **array**.

```
precision (x)
inquiry function precision(x)              ! the decimal precision of x
  integer :: precision
  real :: x                               ! may be any kind, may be complex, may
                                           ! be an array
end function
```

```

present (a)
  inquiry function present(a) ! determine whether an optional argument
                                ! is present
    logical :: present         ! true if a is present, false otherwise
    real :: a                  ! may be any type and kind; a must be an
                                ! optional argument
  end function                 ! of the procedure referencing the
                                ! present function

product (array, dim, mask)
  function product(array,dim,mask) ! product of the elements of array
    real :: product                 ! same type and kind as array
    real :: array(:)               ! may be any kind, any numeric type,
                                    ! and any rank
    integer, optional :: dim        ! if present, 1 ≤ dim ≤ n, where n
                                    ! is rank of array
    logical, optional :: mask      ! if present, mask must have same
                                    ! shape as array
  end function

```

The result is scalar if **dim** is omitted or **array** has rank 1, in which case the value returned is the product of the elements of **array**. If array has rank *n* greater than 1 and **dim** is present, **dim** specifies the dimension along which to compute the products; in this case the result is an array of rank *n*-1 and shape (d1,d2,...,ddim-1, ddim+1,...,dn) where (d1,d2,...,dn) is the shape of **array** and each value of the result is the product of the elements along the **dim** dimension of **array**. If **mask** is present only those elements of **array** corresponding to the true values in **mask** are used in computing the product(s).

```

radix (x)
  inquiry function radix(x)       ! radix (base) of the number model for
                                    ! x
    integer :: radix
    real :: x                     ! may be any kind, any numeric type;
                                    ! may be an array
  end function

```

```

random_number (harvest)
  subroutine random_number(harvest) ! generates one or more pseudorandom
                                      ! numbers
    real, intent(out) :: harvest    ! may be any kind, may be an array
  end subroutine

```

If **harvest** is a scalar, a single pseudorandom number from the uniform distribution between 0 and 1 is generated and assigned to **harvest**; if **harvest** is an array, **size(harvest)** such numbers are generated and assigned to **harvest**.

```
random_seed (size, put, get)
  subroutine random_seed(size,put,get)      ! set or retrieve the
                                           ! random_number seed
                                           ! number of integers (n)
                                           ! used for the value of the
                                           ! seed
                                           ! size(put) must be equal
                                           ! to n; set the seed to put
                                           ! size(get) must be equal
                                           ! to n; retrieve the seed
                                           ! into get
                                           ! a given call to
                                           ! random_seed has at most
                                           ! one argument

  integer, optional, intent(out) :: size
  integer, optional, intent(in)  :: put(:)
  integer, optional, intent(out) :: get(:)

end subroutine
```

If a call to **random_seed** is made without any arguments, the seed is set to an implementation determined value. When the argument is **put**, the seed is reinitialized to this value; when the argument is **get**, the current value of the seed is retrieved.

```
range (x)
  inquiry function range(x) ! decimal exponent range for x
  integer :: range          ! value is int(log10(huge(x))) - but see
                           ! comment below
  real :: x                 ! may be any kind, any numeric type; may be
                           ! an array

end function
```

If **x** is of type integer, **huge(x)** returns an integer, which is not legal for **log10**; the effect for **range** is, however, as if the equivalent real value had been returned for **huge**. If **x** is of type real the value actually returned by **range** is $\min(\text{int}(\log_{10}(\text{huge}(x))), -\text{int}(\log_{10}(\text{tiny}(x))))$.

```
real (a, kind)
  elemental function real(a,kind) ! convert a to the equivalent real
                                  ! value of specified kind
  real(kind) :: real              ! the converted real value
  real :: a                       ! may be any kind and any numeric
                                  ! type
  integer, optional :: kind       ! if present, must be a scalar
                                  ! initialization expression

end function ! if kind is absent, the result kind is default real
```

If **a** is of type real, the result is this same value, but possibly of a different kind. If **a** is an integer, the equivalent real value is returned. If **a** is complex, the result is the real part of **a**.

```
repeat (string, ncopies)
  function repeat(string,ncopies)      ! concatenate several
                                       ! copies of a string
  character(len(string)*ncopies) :: repeat ! ncopies of string
                                       ! concatenated ; same kind
                                       ! as string
  character(*) :: string               ! may be any kind
  integer :: ncopies                   !  $0 \leq \text{ncopies}$ 

end function
```

```

reshape (source, shape, pad, order)
  function reshape(source,shape,pad,order)      ! reshape source into the
                                                    ! array shape specified
                                                    ! shape
                                                    ! same type and kind as
                                                    ! source, with shape shape
  real :: reshape(:)                            ! may be any type, kind,
                                                    ! and rank
  real :: source(:)                              ! all element values must
                                                    ! be positive
  integer :: shape(:)                          ! same type and kind as
                                                    ! source; may be any rank
  real, optional :: pad(:)                    ! a permutation of (1, 2,
                                                    ! 3, ..., size(shape))
  integer, optional :: order(size(shape))
  end function

```

Values are copied from **source** (and then, if needed, from **pad**) to **reshape**, in array element order. If **size(source) > product(shape)**, the extra values of **source** are ignored. If **size(source) < product(shape)**, **pad** must be supplied, with **size(pad) ≥ product(shape)-size(source)**. If **order** is present it specifies the array element order of the **reshape** subscripts.

```

rrspacing (x)
  elemental function rrspacing(x)      ! reciprocal of the relative spacing
                                                    ! of values near x
  real :: rrspacing                    ! value is x/(nearest(x,1.)-x) for x
                                                    ! > 0
  real :: x
  end function

```

```

scale (x, i)
  elemental function scale(x,i)      ! scales x by a specified amount
  real :: scale                        ! same kind as x; value is
                                                    ! x*radix(x)**i
  real :: x                            ! may be any kind
  integer :: i                         ! scaling may be up (i > 0) or down
                                                    ! (i < 0) (or i may be zero)
  end function

```

```

scan (string, set, back)
  elemental function scan(string,set,back) ! search string for an
                                                    ! occurrence of any
                                                    ! character in set
  integer :: scan                      ! value is first such
                                                    ! position in string
  character(*) :: string                ! may be any kind
  character(*) :: set                   ! same kind as string
  logical, optional :: back           ! if present and true,
                                                    ! search is from back of
                                                    ! string instead
  end function                          ! if no match, zero is
                                                    ! returned

```

```
selected_int_kind (r)
  function selected_int_kind(r)      ! determines kind value for specified
                                     ! integer range
    integer :: selected_int_kind    ! the kind value, or -1 if there is no
                                     ! such integer type
    integer :: r                    ! specifies an integer range of at
                                     ! least -10**r to +10**r
  end function
```

If more than one integer type meets the criteria, the kind value for the one with the smallest decimal exponent range is returned or, if there are several such, the smallest of these kind values.

```
selected_real_kind (p, r)
  function selected_real_kind(p,r)   ! determines kind value for real
                                     ! type with specified properties
    integer :: selected_real_kind    ! the kind value, or a negative
                                     ! value if there is no such real
                                     ! type
    integer, optional :: p           ! specifies a real type with at
                                     ! least p decimal digits of
                                     ! precision
    integer, optional :: r           ! specifies an exponent range of at
                                     ! least 10**-r to 10**r
  end function                       ! at least one argument must be
                                     ! present
```

The result is the kind type parameter of a real data type with decimal precision, as returned by the **precision** function, of at least **p** digits and a decimal exponent range, as returned by the **range** function, of at least **r**; if no such type is available on the processor, the result is -1 if the precision is not available, -2 if the exponent range is not available, and -3 if neither is available. If more than one real type meets the criteria, the kind value for the one with the smallest decimal precision is returned or, if there are several such, the smallest of these kind values.

```
set_exponent (x, i)
  elemental function set_exponent(x,i) ! a value with the fractional
                                     ! part of x and exponent i
    real :: set_exponent              ! same kind as x; value is
                                     ! x*radix(x)**(i-exponent(x))
    real :: x                        ! may be any kind
    integer :: i                     ! i may be positive, negative,
                                     ! or zero
  end function
```

```

shape (source)
  inquiry function shape(source) ! determine the shape of an array
    integer :: shape(:)          ! element values are the extents of
                                ! source
    real :: source(:)           ! may be any type, kind, and rank; may
                                ! be scalar
  end function

```

The value of the *k*th element of **shape** is the size of the *k*th dimension of **source**. **size(shape)** is *n*, where *n* is the rank of **source**; if **source** is a scalar, *n* is zero. **source** must not be a disassociated pointer array, an unallocated allocatable array, or an assumed-size array.

```

sign (a, b)
  elemental function sign(a,b) ! set the sign of a value
    real :: sign                ! value is |a| if b ≥ 0, -|a| if b < 0;
                                ! type and kind of a
    real :: a                   ! may be any kind; may be integer
    real :: b                   ! same type and kind as a
  end function

```

```

sin (x)
  elemental function sin(x)    ! the sine of x
    real :: sin                ! same type and kind as x
    real :: x                  ! may be complex
  end function

```

If **x** is of type real, it is regarded as a value in radians; if **x** is of type complex, its real part is regarded as a value in radians.

```

sinh (x)
  elemental function sinh(x) ! the hyperbolic sine of x;
    real :: sinh              ! may be complex
    real :: x
  end function

```

```

size (array, dim)
  inquiry function size(array,dim) ! determine number of elements in (a
    integer :: size                ! dimension of) an array
                                ! value is product(shape(array)) if
                                ! dim is absent
    real :: array(:)               ! may be any type, kind, and rank
    integer, optional :: dim       ! if present, 1 ≤ dim ≤ n, where n
                                ! is the rank of array, and
    end function                  ! the returned value is the extent
                                ! of the dim dimension

```

```

spacing (x)
  elemental function spacing(x) ! absolute spacing near x
    real :: spacing              ! value is nearest(x,1.)-x for x > 0
    real :: x
  end function

```

```
spread (source, dim, ncopies)
  function spread(source,dim,ncopies) ! makes ncopies of source along a
                                     ! new dimension
    real :: spread(:, :)             ! same type and kind as source;
                                     ! rank 1 greater than source
    real :: source(:)                ! may be any type, kind, and
                                     ! rank; may be scalar
    integer :: dim                    !  $1 \leq \text{dim} \leq n+1$ , where  $n$  is the
                                     ! rank of source
    integer :: ncopies                ! number of copies to spread is
                                     !  $\max(0, \text{ncopies})$ 
  end function
```

spread broadcasts several copies of **source** along a specified dimension (as in forming a book from copies of a single page) and thus forms an array of rank one greater than **source**. If **source** is a scalar then **spread** is an array of rank one and size $\max(0, \text{ncopies})$ and all element have the value of **source**. If **source** is an array with shape (d_1, d_2, \dots, d_n) , **spread** has shape $(d_1, d_2, \dots, d_{\text{dim}-1}, \max(0, \text{ncopies}), d_{\text{dim}}, d_{\text{dim}+1}, \dots, d_n)$.

```
sqrt (x)
  elemental function sqrt(x) ! the square root of x
    real :: sqrt             ! same type and kind as x; value is
    real :: x                ! may be complex
  end function                ! if x is of type real,  $x > 0$ 
```

If **x** is complex, the real part of the result is nonnegative; if the real part is zero, the imaginary part is nonnegative.

```
sum (array, dim, mask)
  function sum(array,dim,mask) ! sum of the elements of array
    real :: sum                ! same type and kind as array
    real :: array(:)           ! may be any kind, any numeric type,
                                ! and any rank
    integer, optional :: dim    ! if present,  $1 \leq \text{dim} \leq n$ , where  $n$  is
                                ! rank of array
    logical, optional :: mask  ! if present, mask must have same shape
                                ! as array
  end function
```

The result is scalar if **dim** is omitted or **array** has rank 1, in which case the value returned is the sum of the elements of **array**. If array has rank n greater than 1 and **dim** is present, $1 \leq \text{dim} \leq n$ and **dim** specifies the dimension along which to compute the sums; in this case the result is an array of rank $n-1$ and shape $(d_1, d_2, \dots, d_{\text{dim}-1}, d_{\text{dim}+1}, \dots, d_n)$ where (d_1, d_2, \dots, d_n) is the shape of **array** and each value of the result is the sum of the elements along the **dim** dimension of **array**. If **mask** is present only those elements of **array** corresponding to the true values in **mask** are used in computing the sum(s).

```

system_clock (count, count_rate, count_max)
  subroutine system_clock(count,count_rate,count_max) ! integer data
                                                    ! from a real-time
                                                    ! clock
      integer, intent(out), optional :: count      ! 0 ≤ count ≤ count_max
      integer, intent(out), optional :: count_rate ! clock counts per
                                                    ! second
      integer, intent(out), optional :: count_max  ! the maximum count can
                                                    ! have

  end subroutine

```

All values are processor dependent; **count_rate** indicates how many times **count** is incremented each second; when it reaches **count_max**, it resets to zero. If there is no processor clock **count** always returns -huge(0), **count_rate** returns zero, and **count_max** returns zero.

```

tan (x)
  elemental function tan(x)      ! the tangent of x
    real :: tan
    real :: x                    ! value is assumed to be radians, may be
                                ! complex
  end function

```

```

tanh (x)
  elemental function tanh(x)     ! the hyperbolic tangent of x
    real :: tanh                 ! may be complex
    real :: x
  end function

```

```

tiny (x)
  inquiry function tiny(x)       ! the smallest positive value for the type
                                ! and kind of x
    real :: tiny ! same kind as x
    real :: x ! may be any kind; may be an array
  end function

```

```

transfer (source, mold, size)
  function transfer(source,mold,size) ! same bit pattern, but different
                                      ! type/kind
    real :: transfer                  ! bit pattern of source;
                                      ! type/kind of mold; may be an
                                      ! array
    real :: source                    ! may be any type and kind; may
                                      ! be scalar or array
    real :: mold                      ! may be any type and kind; may
                                      ! be scalar or array
    integer, optional :: size         ! specifies the shape of the
                                      ! result; the value must be
                                      ! positive

  end function

```

If **mold** is scalar and **size** is absent the result is scalar. If **mold** is an array and **size** is absent the result is a rank 1 array; its size is the smallest possible to hold all of the bits of **source**. If **size** is present, the result is a rank 1 array of this size; if this makes transfer

longer than source, the extra part of transfer is undefined and if it makes transfer shorter than source the extra bits of source are not transferred.

```
transpose (matrix)
  function transpose(matrix)                ! transpose matrix
    real :: transpose(size(matrix,2),size(matrix,1)) ! element (i,j) is
                                                    ! matrix(j,i)
    real :: matrix(:, :)                    ! may be any type
                                                    ! and kind
  end function

trim (string)
  function trim(string)                    ! removes trailing blanks from a string
    character(*) :: trim                  ! same as string, except all trailing
                                                    ! blanks removed
    character(*) :: string                ! may be any kind
  end function

ubound (array, dim)
  inquiry function ubound(array,dim)      ! the upper bound(s) of array
    integer :: ubound                    ! scalar if dim is present; a
                                                    ! rank one array otherwise
    real :: array(:)                    ! may have any type, kind, and
                                                    ! rank
    integer, optional :: dim              ! if present,  $1 \leq \text{dim} \leq n$ , where
                                                    !  $n$  is the rank of array
  end function
```

If **dim** is present the result is a scalar and is the upper bound of **array** along the dimension **dim**. If **dim** is absent the result is a one-dimensional array whose size is the rank of **array**, and the value of each element of the result is the upper bound of that dimension of **array**. If **array** is an array expression other than an array name (e.g., an array section), the upper bound value is based on the lower bound value being 1.

```
unpack (vector, mask, field)
  function unpack(vector,mask,field)      ! unpack a vector into an array,
                                                    ! under control of a mask
    real :: unpack(:)                    ! same type and kind as vector;
                                                    ! same shape as mask
    real :: vector(:)                    ! may be any type and kind
    logical :: mask(:)                   ! may be any rank
    real :: field(size(mask))             ! same type and kind as vector;
                                                    ! same shape as mask -
  end function                            ! field may be a scalar, in which
                                                    ! case it is broadcast
```

The element of the result that corresponds to the k th true element of **mask**, in array element order, is **vector(k)**, for all the true values in **mask**. Each other element of the result is the value of the corresponding element of **field**.

```

verify (string, set, back)
  elemental function verify(string,set,back)
    integer :: verify
    character(*) :: string
    character(*) :: set
    logical, optional :: back
  end function

```

! check that **set** contains
! all the characters in
! **string**
! value is first position
! in **string** that is not a
! **set** character
! may be any kind
! same kind as **string**
! if present and true,
! check is from back of
! **string** instead
! if all characters in
! **string** are in **set**, zero
! is returned

Appendix A

ASCII Table

ASCII codes 0 through 31 are control codes that may or may not have meaning on Linux. They are listed for historical reasons and may aid when porting code from other systems. Codes 128 through 255 are extensions to the 7-bit ASCII standard and the symbol displayed depends on the font being used; the symbols shown below are from the Times New Roman font. The Dec, Oct, and Hex columns refer to the decimal, octal, and hexadecimal numerical representations.

Character	Dec	Oct	Hex	Description	Character	Dec	Oct	Hex	Description

Appendix B

Exceptions and IEEE Arithmetic

Three modules are provided to support floating-point exceptions and IEEE arithmetic: `IEEE_FEATURES`, `IEEE_ARITHMETIC`, and `IEEE_EXCEPTIONS`. Use of these modules and the procedures in them ensure portability of programs exploiting features of IEEE arithmetic across platforms. The module `IEEE_ARITHMETIC` contains a `USE` statement for `IEEE_EXCEPTIONS`. Any procedure that uses `IEEE_ARITHMETIC` will have access to the public features of `IEEE_EXCEPTIONS`.

`IEEE_FEATURES`

This module defines the derived type `IEEE_FEATURES_TYPE` whose components are all private. Its purpose is to express the need for particular IEEE features.

`IEEE_FEATURES_TYPE`

The only possible values are the following constants:

<code>IEEE_DATATYPE</code>	IEEE data types are available
<code>IEEE_DENORMAL</code>	IEEE denormalized values are supported
<code>IEEE_DIVIDE</code>	IEEE division to the required precision is supported
<code>IEEE_HALTING</code>	control of halting is supported
<code>IEEE_INEXACT_FLAG</code>	inexact exceptions are supported.
<code>IEEE_INF</code>	IEEE infinities (positive and negative) are supported
<code>IEEE_INVALID_FLAG</code>	invalid exceptions are supported
<code>IEEE_NAN</code>	IEEE NaN (Not a Number) values are supported
<code>IEEE_ROUNDING</code>	all IEEE rounding modes are supported
<code>IEEE_SQRT</code>	SQRT is supported to the IEEE standard
<code>IEEE_UNDERFLOW_FLAG</code>	underflow exceptions supported

IEEE_ARITHMETIC

This module defines the two derived types `IEEE_CLASS_TYPE` and `IEEE_ROUND_TYPE` whose components are all private. The purpose of `IEEE_CLASS_TYPE` is to identify the class of a value. The purpose of `IEEE_ROUND_TYPE` is to specify or inquire the rounding mode. This module also defines two elemental operators for each of these types: `==` and `/=`. The `==` operator returns true if two values of these types are equal and false if they are not. The `/=` operator returns true if two values of these types are not equal and false if they are equal.

The `IEEE_ARITHMETIC` module further provides a number of subroutines and functions for inquiry, performing operations, and setting the IEEE rounding environment.

IEEE_CLASS_TYPE

The only possible values are the following constants:

<code>IEEE_SIGNALING_NAN</code>	NaN (Not a Number)
<code>IEEE_QUIET_NAN</code>	NaN (Not a Number)
<code>IEEE_NEGATIVE_INF</code>	negative infinity
<code>IEEE_NEGATIVE_NORMAL</code>	negative number
<code>IEEE_NEGATIVE_DENORMAL</code>	negative number smaller than the normal representation
<code>IEEE_NEGATIVE_ZERO</code>	negative zero
<code>IEEE_POSITIVE_ZERO</code>	zero
<code>IEEE_POSITIVE_DENORMAL</code>	positive number smaller than the normal representation
<code>IEEE_POSITIVE_NORMAL</code>	positive number
<code>IEEE_POSITIVE_INF</code>	positive infinity

IEEE_ROUND_TYPE

The only possible values are the following constants:

IEEE_NEAREST

IEEE_TO_ZERO

IEEE_UP

IEEE_DOWN

Subroutines and Functions

The `IEEE_ARITHMETIC` module provides the following *inquiry* functions:

logical function **IEEE_SUPPORT_DATATYPE**(x)
 real(kind=any), intent(in), optional :: x

returns the value `.TRUE.` if the data type of the argument is supported in conformance with section 14.8 of the Fortran 2003 Draft Standard.

logical function **IEEE_SUPPORT_DENORMAL**(x)
 real(kind=any), intent(in), optional :: x

returns the value `.TRUE.` if denormalized numbers are supported for the data type of the argument.

logical function **IEEE_SUPPORT_DIVIDE**(x)
 real(kind=any), intent(in), optional :: x

returns the value `.TRUE.` if division to the accuracy specified by the IEEE standard is supported for the data type of the argument.

logical function **IEEE_SUPPORT_INF**(x)
 real(kind=any), intent(in), optional :: x

returns the value `.TRUE.` if infinities numbers are supported for the data type of the argument.

logical function **IEEE_SUPPORT_IO**(x)
 real(kind=any), intent(in), optional :: x

returns the value `.TRUE.` if IEEE rounding is supported during formatted input and output conversions for the data type of the argument.

```
logical function IEEE_SUPPORT_NAN(x)
real(kind=any), intent(in), optional :: x
```

returns the value `.TRUE.` if NaN (Not a Number) values are supported for the data type of the argument.

```
logical function IEEE_SUPPORT_ROUNDING(round_value, x)
type(IEEE_ROUND_TYPE), intent(in) :: round_value
real(kind=SP), intent(in), optional :: x
```

returns the value `.TRUE.` if the specified rounding type is supported for the data type of the argument.

```
logical function IEEE_SUPPORT_SQRT(x)
real(kind=any), intent(in), optional :: x
```

returns the value `.TRUE.` if `SQRT` to the accuracy specified by the IEEE standard is supported for the data type of the argument.

```
logical function IEEE_SUPPORT_STANDARD(x)
real(kind=any), intent(in), optional :: x
```

returns the value `.TRUE.` if all capabilities and facilities specified by the IEEE standard are supported for the data type of the argument.

```
logical function IEEE_SUPPORT_UNDERFLOW(x)
real(kind=any), intent(in), optional :: x
```

returns the value `.TRUE.` if control of underflow mode is supported for the data type of the argument. Control of underflow mode allows specifying gradual or abrupt underflow. On some processors, chopped underflow can produce code that executes faster.

The `IEEE_ARITHMETIC` module provides the following *elemental* functions for data values that `IEEE_SUPPORT_DATATYPE(x)` returns `.TRUE.`:

```
elemental type(IEEE_CLASS_TYPE) function IEEE_CLASS(x)
real(kind=any), intent(in) :: x
```

returns the class of the input argument `x`.

elemental real function **IEEE_COPY_SIGN**(*x*, *y*)
 real(kind=any), intent(in) :: *x*, *y*

returns a result that has the value of *x* and the sign of *y*, even when *x* is a special value such as NaN or infinity.

elemental logical function **IEEE_IS_FINITE**(*x*)
 real(kind=any), intent(in) :: *x*

returns the value `.TRUE.` if the value of *x* is finite. That is its class is one of:

IEEE_NEGATIVE_NORMAL	IEEE_POSITIVE_DENORMAL
IEEE_NEGATIVE_DENORMAL	IEEE_POSITIVE_NORMAL
IEEE_NEGATIVE_ZERO	IEEE_POSITIVE_ZERO

elemental logical function **IEEE_IS_NAN**(*x*)
 real(kind=any), intent(in) :: *x*

returns the value `.TRUE.` if the value of *x* is a NaN.

elemental logical function **IEEE_IS_NORMAL**(*x*)
 real(kind=any), intent(in) :: *x*

returns the value `.TRUE.` if the value of *x* is normal. That is its class is one of:

IEEE_NEGATIVE_NORMAL	IEEE_POSITIVE_NORMAL
IEEE_NEGATIVE_ZERO	IEEE_POSITIVE_ZERO

elemental logical function **IEEE_IS_NEGATIVE**(*x*)
 real(kind=any), intent(in) :: *x*

returns the value `.TRUE.` if the value of *x* is negative. That is its class is one of:

IEEE_NEGATIVE_NORMAL	IEEE_NEGATIVE_ZERO
IEEE_NEGATIVE_DENORMAL	IEEE_NEGATIVE_INFINITY

elemental real function **IEEE_LOGB**(*x*)
 real(kind=any), intent(in) :: *x*

returns the unbiased exponent of *x* as a floating-point value. If *x* is 0.0, -infinity is returned and `IEEE_DIVIDE_BY_ZERO` is signaled.

elemental real function **IEEE_NEXT_AFTER**(*x*, *y*)
 real(kind=any), intent(in) :: *x*, *y*

returns the neighbor of *x* in the direction of *y*. The *kind* of the result is the same as *x*. If *x* is 0.0, the result is the smallest denormalized number.

elemental real function **IEEE_REM**(x, y)
real(kind=any), intent(in) :: x, y

returns the exact remainder of x/y . The function is defined as $x-y*n$ where n is the nearest integer to x/y . If $|n-x/y| = \frac{1}{2}$, n is even. The *kind* of the result is the same as x .

elemental real function **IEEE_RINT**(x)
real(kind=any), intent(in) :: x

returns the rounded to integer value of x . x is rounded according to the current rounding mode.

elemental real function **IEEE_SCALB**(x, i)
real(kind=any), intent(in) :: x
integer (kind=4), intent(in) :: i

returns the floating-point value of $x*2**i$. The *kind* of the result is the same as x .

elemental logical function **IEEE_UNORDERED**(x, y)
real(kind=any), intent(in) :: x, y

returns if either x or y is a NaN.

elemental real function **IEEE_VALUE**(x, class)
real(kind=any), intent(in) :: x
type(IEEE_CLASS_TYPE), intent(in) :: class

returns a value of the specified IEEE_CLASS_TYPE.

The IEEE_ARITHMETIC module provides the following non-*elemental* subroutines:

subroutine **IEEE_GET_ROUNDING_MODE**(round_value)
type(IEEE_ROUND_TYPE), intent(out) :: round_value

the current rounding mode is returned in the round_value variable.

subroutine **IEEE_GET_UNDERFLOW_MODE**(gradual)
logical(kind=4), intent(out) :: gradual

the current underflow mode (gradual/abrupt) is returned in the gradual variable. If the mode is gradual, the value of gradual will be set to .TRUE.. If IEEE_SUPPORT_UNDERFLOW_CONTROL(x) returns .FALSE., this subroutine will produce a runtime error and should not be called.

```
subroutine IEEE_SET_ROUNDING_MODE(round_value)
type(IEEE_ROUND_TYPE), intent(in) :: round_value
```

the rounding mode is set to the mode specified in the `round_value` variable.

```
subroutine IEEE_SET_UNDERFLOW_MODE(gradual)
logical(kind=4), intent(in) :: gradual
```

the underflow mode is set to gradual if the value of the `gradual` variable is `.TRUE.`. If the value of the `gradual` variable is `.FALSE.`, the underflow mode is set to abrupt. If `IEEE_SUPPORT_UNDERFLOW_CONTROL(x)` returns `.FALSE.` this subroutine will produce a runtime error and should not be called.

The `IEEE_ARITHMETIC` module provides the following *kind* function:

```
integer(kind=4) function IEEE_SELECTED_REAL_KIND(p, r)
integer(kind=4), intent(in), optional :: p
integer(kind=4), intent(in), optional :: r
```

returns the *kind* of an IEEE floating-point value with the requested precision and exponent range. This function is similar to `SELECTED_REAL_KIND`, but only returns IEEE reals.

IEEE_EXCEPTIONS

This module defines the two derived types `IEEE_FLAG_TYPE` and `IEEE_STATUS_TYPE` whose components are all private. The purpose of `IEEE_FLAG_TYPE` is to identify the exception flags. The purpose of `IEEE_STATUS_TYPE` is to save and restore the current floating-point environment.

The `IEEE_EXCEPTIONS` module also provides a number of subroutines and functions for inquiry and getting and setting exception flags.

An important feature of exception flags is that they may or may not halt execution of the program depending on the state of the halting modes. A floating-point operation (such as divide-by-zero) will cause an exception flag to signal, but unless the halting mode for that flag is set to true, execution will continue with an IEEE default value. The `IEEE_GET_FLAG` subroutine can be used to retrieve the current state (signaling or quiet) of a specific exception flag.

IEEE_FLAG_TYPE

The only possible values are the following constants:

IEEE_INVALID

IEEE_OVERFLOW

IEEE_DIVIDE_BY_ZERO

IEEE_UNDERFLOW

IEEE_INEXACT

and the array constants:

IEEE_USUAL

```
type(IEEE_FLAG_TYPE), parameter, dimension(3) :: IEEE_USUAL = &  
    (/IEEE_OVERFLOW, IEEE_DIVIDE_BY_ZERO, IEEE_INVALID/)
```

IEEE_ALL

```
type(IEEE_FLAG_TYPE), parameter, dimension(5) :: IEEE_ALL = &  
    (/IEEE_USUAL, IEEE_UNDERFLOW, IEEE_INEXACT/)
```

IEEE_STATUS_TYPE

This type is used to save and restore the floating-point environment.

Subroutines and Functions

The `IEEE_EXCEPTIONS` module provides the following *elemental* subroutines:

```
elemental subroutine IEEE_GET_FLAG(flag, flag_value)  
type(IEEE_FLAG_TYPE), intent(in) :: flag  
logical(kind=4), intent(out) :: flag_value
```

retrieves the state of the specified flag. If the flag is signaling, `flag_value` is set to `.TRUE..` If the flag is quiet, `flag_value` is set to `.FALSE..`

```

elemental subroutine IEEE_GET_HALTING_MODE(flag, halting)
type(IEEE_FLAG_TYPE), intent(in) :: flag
logical(kind=4), intent(out) :: halting

```

retrieves the halting mode of the specified flag. If the `flag` mode is halting, `halting` is set to `.TRUE.`. If the `flag` mode is continue, `halting` is set to `.FALSE.`.

The `IEEE_EXCEPTIONS` module provides the following non-*elemental* subroutines:

```

subroutine IEEE_GET_STATUS(status_value)
type(IEEE_STATUS_TYPE) :: status_value

```

retrieves the state of the floating-point environment.

```

subroutine IEEE_SET_FLAG(flag, flag_value)
type(IEEE_FLAG_TYPE), intent(in) :: flag
logical(kind=4), intent(in) :: flag_value

```

sets the state of the specified flag. If `flag_value` is `.TRUE.`, the `flag` is set to signaling. If `flag_value` is `.FALSE.`, the `flag` is set to quiet.

```

elemental subroutine IEEE_SET_HALTING_MODE(flag, halting)
type(IEEE_FLAG_TYPE), intent(in) :: flag
logical(kind=4), intent(in) :: halting

```

sets the halting mode of the specified flag. If `halting` is `.TRUE.`, the `flag` mode is set to halting. If `halting` is `.FALSE.`, the `flag` mode is set to continue.

```

subroutine IEEE_SET_STATUS(status_value)
type(IEEE_STATUS_TYPE) :: status_value

```

sets the state of the floating-point environment.

EXAMPLES

The following example demonstrates the sequence necessary to exercise program control over detection of an exception.

```
subroutine safe_divide(a, b, c, fail)
use IEEE_EXCEPTIONS
real a, b, c
logical fail
type(IEEE_STATUS_TYPE) status

! save the current floating-point environment, turn halting for
! divide-by-zero off, and clear any previous divide-by-zero flag
call IEEE_GET_STATUS(status)
call IEEE_SET_HALTING_MODE(IEEE_DIVIDE_BY_ZERO, .false.)
call IEEE_SET_FLAG(IEEE_DIVIDE_BY_ZERO, .false.)

! perform the operation
c = a/b

      ! determine if a failure occurred and restore the floating-point
      ! environment
call IEEE_GET_FLAG(IEEE_DIVIDE_BY_ZERO, fail)
call IEEE_SET_STATUS(value)

end subroutine safe_divide
```

Appendix C

Language Binding Modules

ISO_FORTRAN_ENV MODULE

The ISO_FORTRAN_ENV provides constants and functions describing the Fortran environment to assist in porting source code between different Fortran compilers. All constants in the module are default integer kind, INTEGER(KIND=4), values except the CHARACTER functions COMPILER_VERSION() and COMPILER_OPTIONS().

NAME	DESCRIPTION
CHARACTER_STORAGE_SIZE	Size in bits of a character
COMPILER_VERSION()	Character scalar result describing the compiler version at the compile time
COMPILER_OPTIONS()	Character scalar result describing the compiler options at the compile time
ERROR_UNIT	Preconnected unit used for error reporting
FILE_STORAGE_SIZE	Size in bits of the file storage unit
INPUT_UNIT	Preconnected unit used for input
INT8	Kind of 8 bit integer
INT16	Kind of 16 bit integer
INT32	Kind of 32 bit integer
INT64	Kind of 64 bit integer
INTEGER_KINDS	Rank 1 integer array of available integer kinds
IOSTAT_END	Value of IOSTAT= on end-of-file
IOSTAT_EOR	Value of IOSTAT= on end-of-record
LOGICAL_KINDS	Rank 1 integer array of available logical kinds
NUMERIC_STORAGE_SIZE	Size in bits of numeric storage unit
OUTPUT_UNIT	Preconnected unit used for output
REAL32	Kind of 32 bit real
REAL64	Kind of 64 bit real
REAL128	Kind of 128 bit real
REAL_KINDS	Rank 1 integer array of available real kinds

ISO_C_BINDING MODULE

The ISO_C_BINDING module, part of the Fortran 2003 standard, provides constants, types, and procedures that are useful in programs which are built using a mix of C and Fortran routines.

KIND Parameters

The KIND parameters contained in the ISO_C_BINDING module provide interoperability between Fortran intrinsic types and C types. The KIND parameters are all of type INTEGER(KIND=1) and are summarized in the table below.

FORTTRAN TYPE	KIND NAME	C TYPE
INTEGER	C_INT	int
	C_SHORT	short
	C_LONG	long
	C_LONG_LONG	long long
	C_SIGNED_CHAR	signed char
	C_SIZE_T	size_t
FORTTRAN TYPE	KIND NAME	C TYPE
INTEGER	C_INT8_T	int8_t
	C_INT16_T	int16_t
	C_INT32_T	int32_t
	C_INT64_T	int64_t
	C_INT_LEAST8_T	int_least8_t
	C_INT_LEAST16_T	int_least16_t
	C_INT_LEAST32_T	int_least32_t
	C_INT_LEAST64_T	int_least64_t
	C_INT_FAST8_T	int_fast8_t
	C_INT_FAST16_T	int_fast16_t
	C_INT_FAST32_T	int_fast32_t
	C_INT_FAST64_T	int_fast64_t
	C_INTMAX_T	intmax_t
	C_INTPTR_T	intptr_t
REAL	C_FLOAT	float
	C_DOUBLE	double
	C_LONG_DOUBLE	long double
	C_FLOAT_COMPLEX	float_Complex
	C_DOUBLE_COMPLEX	double_Complex
	C_LONG_DOUBLE_COMPLEX	long double_Complex
LOGICAL	C_BOOL	_Bool
CHARACTER	C_CHAR	char

CHARACTER CONSTANTS

The ISO_C_BINDING module provides character constants for C character values used as escape sequences. These constants are of type CHARACTER(LEN=1) and are summarized in the table below.

NAME	DEFINITION	C CHARACTER
C_NULL_CHAR	null character	'\0'
C_ALERT	alert	'\a'
C_BACKSPACE	backspace	'\b'
C_FORM_FEED	form feed	'\f'
C_NEW_LINE	new line	'\n'
C_CARRIAGE_RETURN	carriage return	'\r'
C_HORIZONTAL_TAB	horizontal tab	'\t'
C_VERTICAL_TAB	vertical tab	'\v'

POINTER CONSTANTS

The ISO_C_BINDING module defines the constant C_NULL_PTR that is of type C_PTR and has the value of a C null pointer. The module also defines the constant C_NULL_FUNPTR that is of type C_FUNPTR and has the value of C null function pointer.

TYPE DEFINITIONS

The ISO_C_BINDING module defines two data types: C_PTR and C_FUNPTR. The C_PTR type is interoperable with any C data pointer. The C_FUNPTR type is interoperable with a C function pointer. The components of both types are private and not visible to code that uses the ISO_C_BINDING module.

PROCEDURES

The ISO_C_BINDING module provides five procedures to facilitate interoperability with the C language: C_ASSOCIATED, C_F_POINTER, C_F_PROCPOINTER, C_FUNLOC and C_LOC.

The C_ASSOCIATED function is use to determine if a variable of type C_PTR or C_FUNPTR has been pointer associated. It is also used to compare the values of two variables of type C_PTR (or two variables of type C_FUNPTR) for equality.

```
logical function c_associated(c_ptr1,c_ptr2)
type(C_PTR), intent(in) :: c_ptr1
type(C_PTR), intent(in), optional :: c_ptr2
```

```
logical function c_associated(c_fun_ptr1,c_fun_ptr2)
type(C_FUNPTR), intent(in) :: c_fun_ptr1
type(C_FUNPTR), intent(in), optional :: c_fun_ptr2
```

When called with one argument, `C_ASSOCIATED` returns the value `.FALSE.` if the argument is a C null pointer and `.TRUE.` otherwise. When called with two arguments, `C_ASSOCIATED` returns the value `.TRUE.` if the arguments compare equal to each other and `.FALSE.` otherwise.

The `C_F_POINTER` subroutine is used to associate a Fortran variable of type `C_PTR` with a C pointer variable.

```
subroutine C_F_POINTER(cptr,fptra,shape)
type(C_PTR), intent(in) :: cptr
any type, pointer, intent(out) :: fptra
integer, dimension( : ),intent(in),optional :: shape
```

The value of `cptr` is the address of an interoperable data entity or the result of a reference to the `C_LOC` function with a noninteroperable argument. The value of `cptr` must not be the C address of a Fortran variable that does not have the `target` attribute.

The argument `fptr` is a pointer. If the value of `cptr` is the C address of an interoperable data entity, `fptr` must be a data pointer with type and type parameters that are interoperable. In this case, `fptr` becomes pointer associated with the target of `cptr`. If `fptr` is an array, its shape is specified by `shape` and each lower bound is 1. If the value of `cptr` is the result of a reference to `C_LOC` with a noninteroperable argument `X`, `fptr` must be a scalar pointer with the same type and type parameters as `X` and `fptr` becomes pointer associated with `X`.

The argument `shape` is present if and only if `fptr` is an array and its size is equal to the rank of `fptr`.

The `C_F_PROCPOINTER` subroutine associates a Fortran variable of type `C_FUNPTR` with the address of a C function.

```
subroutine C_F_PROCPOINTER(cptr,fptr)
  type(C_FUNPTR), intent(in) :: cptr
  integer(kind=intptr_t), intent(out) :: fptr
```

The value of `cptr` is the address of a C procedure which is interoperable and `fptr` is type integer with size large enough to hold the value of `cptr`.

The `C_FUNLOC` function returns the address of an interoperable C procedure as a `C_FUNPTR`.

```
type(C_FUNPTR) function C_FUNLOC(x)
  integer(kind=intptr_t), intent(in) :: x
```

The value of `x` is the address of a procedure which is interoperable. The result is a value that can be used in a call to `C_F_PROCPOINTER`.

The `C_LOC` function returns the C address of its argument.

```
type(C_PTR) function C_LOC(x)
  any type, intent(in) :: x
```

The argument `x` has interoperable type and type parameters and is a variable that has the `TARGET` attribute, is an allocated allocatable array that has the `TARGET` attribute and not of zero size, or is an associated scalar pointer. The argument `x` may also be a scalar with no length type parameters and be a nonallocatable, nonpointer variable that has the `TARGET` attribute, an allocated allocatable variable that has the `TARGET` attribute, or an associated pointer.

Appendix D

Error Messages

This appendix lists runtime error numbers and their meanings. These numbers are assigned to the `STAT=` specifier in `ALLOCATE` statements and to the `IOSTAT=` specifier variable in I/O statements.

ALLOCATE statement errors

10004	attempt to allocate array of requested size failed
10045	attempt to <code>DEALLOCATE</code> an unallocated array
10046	attempt to <code>DEALLOCATE</code> an item with a modified size
10047	attempt to <code>ALLOCATE</code> an array that has already been allocated
10070	attempt to <code>ALLOCATE</code> an unassociated pointer

FORTTRAN I/O errors:

10000	File not open for read
10001	File not open for write
10002	File not found
10003	Record length negative or 0
10004	Buffer allocation failed
10005	Bad iolist specifier
10006	Error in format string
10007	Illegal repeat count
10008	Hollerith count exceeds remaining format string
10009	Format string missing opening "("
10010	Format string has unmatched parens
10011	Format string has unmatched quotes
10012	Non-repeatable format descriptor
10013	Attempt to read past end of file
10014	Bad file specification
10015	Format group table overflow
10016	Illegal character in numeric input
10017	No record specified for direct access
10018	Maximum record number exceeded
10019	Illegal file type for namelist directed I/O
10020	Illegal input for namelist directed I/O
10021	Variable not present in current namelist
10022	Variable type or size does not match edit descriptor
10023	Illegal direct access record number
10024	Illegal use of internal file
10025	<code>RECL=</code> only valid for direct access files

10026	BLOCK= only valid for unformatted sequential files
10027	Unable to truncate file after rewind, backspace, or endfile
10028	Can't do formatted I/O on an entire structure
10029	Illegal (negative) unit specified
10030	Specifications in re-open do not match previous open
10031	No implicit OPEN for direct access files
10032	Cannot open an existing file with STATUS='NEW'
10033	Command not allowed for unit type
10034	MRWE is required for that feature
10035	Bad specification for window
10036	Endian specifier not BIG_ENDIAN or LITTLE_ENDIAN
10037	Cannot ENDIAN convert entire structures
10038	Attempt to read past end of record
10039	Attempt to read past end of record in non-advancing I/O
10040	Illegal specifier for ADVANCE=
10041	Illegal specifier for DELIM=
10042	Illegal specifier for PAD=
10043	SIZE= specified with ADVANCE=YES
10044	EOR= specified with ADVANCE=YES
10045	Cannot DEALLOCATE disassociated pointer or unallocated array
10046	Cannot DEALLOCATE a portion of an original allocation
10047	An allocatable array has already been allocated
10048	Internal or unknown runtime library error
10049	Unknown data type passed to runtime library
10050	Illegal DIM argument to array intrinsic
10051	Size of SOURCE argument to RESHAPE smaller than SHAPE array
10052	SHAPE array for RESHAPE contains a negative value
10053	Unallocated or disassociated array passed to inquiry function
10054	The ncopies argument to REPEAT is negative
10055	The S argument to NEAREST is negative
10056	The ORDER argument to RESHARE contains an illegal value
10057	Result of TRANSFER with no SIZE is smaller than source
10058	SHAPE array for RESHAPE is zero sized array
10059	VECTOR argument to UNPACK contains insufficient values
10060	Attempt to write a record longer than specified record length
10061	ADVANCE= specified for direct access or unformatted file
10062	NAMelist name is longer than specified record length
10063	NAMelist variable name exceeds maximum length
10064	PAD= specified for unformatted file
10065	NAMelist input contains multiple strided arrays
10066	Expected & or \$ as first character for NAMelist input
10067	NAMelist group does not match current input group
10068	Pointer or allocatable array not associated or allocated
10069	NAMelist input contains negative array stride
10070	Runtime memory allocation fails
10071	Illegal rank for matrix argument to MATMUL array intrinsic
10072	Matrix arguments to MATMUL array intrinsic are not conformable

Appendix E

Technical Support

The Absoft Technical Support Group will provide technical assistance to all registered users. They will *not* answer general questions about operating systems, operating system interfaces, graphical user interfaces, or teach the FORTRAN language. For further help on these subjects, please consult this manual and any of the books and manuals listed in the bibliography.

Before contacting Technical Support, please study this manual and the *Fortran User Guide* to make sure your problem is not covered here. Specifically, look at the chapter **Using The Compilers** in the *Pro Fortran User Guide* and the **Error Messages** appendices of both manuals. To help Technical Support provide a quick and accurate solution to your problem, please include the following information in any correspondence or have it available when calling.

Product Information:

- Name of product .
- Version number.
- Serial number.
- Version number of the operating system.

System Configuration:

- Hardware configuration (hard drive, etc.).
- System software release (i.e. 4.0, 3.5, etc).
- Any software or hardware modifications to your system.

Problem Description:

- What happens?
- When does it occur?
- Provide a small (20 line) reproducible program or step-by-step example if possible.

Contacting Technical Support:

Address: Absoft Corporation
 Attn: Technical Support
 2781 Bond Street
 Rochester Hills, MI 48309

Technical Support:	(248) 853-0095	9am - 3pm EST
FAX	(248) 853-0108	24 Hours
email	support@absoft.com	24 Hours
World Wide Web	http://www.absoft.com	

Appendix F

Floating Point Numbers

A floating point number is an approximation of a real number. The model for floating point numbers is:

$$v = s \times r^e \times \sum_{i=0}^q d_i \times r^{i-1}$$

The most common implementation is IEEE P754 single and double precision, where s is ± 1 , q is 24 or 53, r is 2, d is 0 or 1, and $-126 \leq e \leq 127$ or $-1022 \leq e \leq 1023$.

The range of representable single precision number is approximately:

$\pm 0.3402823\text{E}+39$ to $\pm 0.1175494\text{E}-37$

and the range of representable double precision number is approximately:

$\pm 0.1797693134862320\text{D}+309$ to $\pm 0.2225073858507202\text{D}-307$

The number of values in these ranges is finite and not all numbers are representable. For example, just as $1/3$ cannot be stated exactly as a decimal, $1/10$ or 0.1 cannot be represented exactly in IEEE floating point. Because of this potential for inexact representation of real values, the equality relational operators ($=$ and \neq) may at times yield “unreliable” results and thus should be used with care (if at all) with real operands.

Consider the `SQRT` function. The square roots of the values in the interval $(.25, 1.0)$ map into the interval $(0.5, 1.0)$. There are twice as many numbers in the first interval as there are in the second, so on average, the square roots of 2 numbers in the first interval must map into one number in the second.

Floating point numbers have a finite number of digits, either binary or decimal. The $\log_2 10$ is about 3.322 so about 3.322 binary digits are needed to represent a decimal digit.

REAL(4) has a 24 bit mantissa \Rightarrow 7.2 decimal digits

REAL(8) has a 53 bit mantissa \Rightarrow 15.9 decimal digits

The results of operations on numbers with large exponent differences may not be representable. For example, both of the single precision numbers 2.0×10^5 and 2.0×10^{-5} are representable, but their sum is not:

```
200000.0
+  0.00002
200000.0
```

```
a = 2.0*10.0**(+5)
b = 2.0*10.0**(-5)
c = a+b
print *,a, b, c
print *,a /= a+b, a /= c
end
```

```
200000.  2.000000E-05  200000.
T F
```

Loss of precision with floating point numbers is a significant problem with numerically sensitive programs. Consider the sine function. It is defined over the interval $(-\pi/2, \pi/2)$ and returns values in the interval $(0.0, 1.0)$. Range reduction is automatically performed for arguments outside of the interval. However, although range reduction is carefully performed, loss of significant digits can occur to the extent that the function result becomes useless.

```
integer, parameter :: rp = selected_real_kind(6,30)
real(rp) halfpi, a
halfpi = atan(1.0_rp)*2.0_rp
do i=1,7
  a = halfpi * 10.0_rp**i
  print 100,i,a,sin(a)
end do
100  format (i2, f18.6, f10.6)
end
```

```
1      15.707963 -0.000001
2      157.079630  0.000003
3      1570.796300  0.000060
4      15707.963000  0.000599
5      157079.640000  0.007945
6      1570796.300000  0.048186
7      15707964.000000  0.668397
8      157079630.000000 -0.628396
9      1570796400.000000  0.945949
10     15707963000.000000 -0.999123
```

Appendix G

Extensions To Intrinsic Functions

The functions listed in the following table are historical extensions to the Fortran programming language. They are provided as a convenience to porting legacy programs. Their use is not recommended for new programs, as they are non-standard.

Specific Name	Generic Name	Usage	Argument Type	Result Type	Notes
---------------	--------------	-------	---------------	-------------	-------

Type Conversion

IINT	INT	IINT(x)	real	integer*2	
JINT	INT	JINT(x)	real	integer	
KINT	INT	KINT(x)	real	integer*8	
IIFIX	INT	IIFIX(x)	real	integer*2	
HFIX	INT	HFIX(x)	real	integer*2	
KFIX	INT	KFIX(x)	real	integer*8	
JIFIX	INT	JIFIX(x)	real	integer	
IIDINT	INT	IIDINT(d)	double	integer*2	
JIDINT	INT	JIDINT(d)	double	integer	
FLOATI	REAL	FLOATI(i)	integer*2	real	
FLOATJ	REAL	FLOATJ(i)	integer	real	
FLOATK	REAL	FLOATK(i)	integer*8	real	
DREAL	DREAL	DREAL(x)	any	double	
DFLOTI	DBLE	DFLOTI(i)	integer*2	double	
DFLOTJ	DBLE	DFLOTJ(i)	integer	double	
DFLOTK	DBLE	DFLOTK(i)	integer*8	double	
DCMPLX	DCMPLX	DCMPLX(x)	any	complex*16	

Nearest Integer

ININT	NINT	ININT(r)	real	integer*2	
JNINT	NINT	JNINT(r)	real	integer	
KNINT	NINT	KNINT(r)	real	integer*8	
IIDNNT	NINT	IIDNNT(d)	double	integer*2	
JIDNNT	NINT	JIDNNT(d)	double	integer	
KIDNNT	NINT	KIDNNT(d)	double	integer*8	

Absolute Value

IIABS	ABS	IIABS(i)	integer*2	integer*2	
JIABS	ABS	JIABS(i)	integer	integer	
KIABS	ABS	KIABS(i)	integer*8	integer*8	
CDABS	ABS	CDABS(cd)	complex*16	double	

Specific Name	Generic Name	Usage	Argument Type	Result Type	Notes
---------------	--------------	-------	---------------	-------------	-------

Remaindering

IMOD	MOD	IMOD (i, j)	integer*2	integer*2	
JMOD	MOD	JMOD (i, j)	integer	integer	
KMOD	MOD	KMOD (i, j)	integer*8	integer*8	

Transfer of Sign

IISIGN	SIGN	IISIGN (i, j)	integer*2	integer*2	
JISIGN	SIGN	JISIGN (i, j)	integer	integer	
KISIGN	SIGN	KISIGN (i, j)	integer*8	integer*8	

Positive Difference

IIDIM	DIM	IIDIM (i, j)	integer*2	integer*2	
JIDIM	DIM	JIDIM (i, j)	integer	integer	
KIDIM	DIM	KIDIM (i, j)	integer*8	integer*8	

Choosing Largest Value

IMAX0	MAX	IMAX0 (i, j, ...)	integer*2	integer*2	
JMAX0	MAX	JMAX0 (i, j, ...)	integer	integer	
KMAX0	MAX	KMAX0 (i, j, ...)	integer*8	integer*8	
AIMAX0		AIMAX0 (i, j, ...)	integer*2	real	
AJMAX0		AIMAX0 (i, j, ...)	integer	real	
IMAX1		IMAX1 (r, s, ...)	real	integer*2	
JMAX1		JMAX1 (r, s, ...)	real	integer	
KMAX1		KMAX1 (r, s, ...)	real	integer*8	

Choosing Smallest Value

IMIN0	MIN	IMIN0 (i, j, ...)	integer*2	integer*2	
JMIN0	MIN	JMIN0 (i, j, ...)	integer	integer	
KMIN0	MIN	KMIN0 (i, j, ...)	integer*2	integer*2	
AIMIN0		AIMIN0 (i, j, ...)	integer*2	real	
AJMIN0		AIMIN0 (i, j, ...)	integer	real	
IMIN1		IMIN1 (r, s, ...)	real	integer*2	
JMIN1		JMIN1 (r, s, ...)	real	integer	
KMIN1		KMIN1 (r, s, ...)	real	integer*8	

Imaginary Part of Complex

DIMAG		DIMAG (cd)	complex*16	double	
-------	--	------------	------------	--------	--

Conjugate of Complex

DCONJG		DCONJG (cd)	complex*16	complex*16	
--------	--	-------------	------------	------------	--

Specific Name	Generic Name	Usage	Argument Type	Result Type	Notes
---------------	--------------	-------	---------------	-------------	-------

Square Root

CDSQRT	SQRT	CDSQRT (cd)	complex*16	complex*16	
--------	------	-------------	------------	------------	--

Exponential

CDEXP	EXP	CDEXP (cd)	complex*16	complex*16	
-------	-----	------------	------------	------------	--

Natural Logarithm

CDLOG	LOG	CDLOG (cd)	complex*16	complex*16	
-------	-----	------------	------------	------------	--

Common Logarithm

DLOG10	LOG10	DLOG10 (d)	double	double	
--------	-------	------------	--------	--------	--

Sine

SIND	SIND	SIND (r)	real	real	
DSIND	SIND	DSIND (d)	double	double	
CDSIN	SIN	CDSIN (cd)	complex*16	complex*16	

Cosine

COSD	COSD	COSD (r)	real	real	
DCOSD	COSD	DCOSD (d)	double	double	
CDCOS	COS	CDCOS (cd)	complex*16	complex*16	

Tangent

TAND	TAND	TAND (r)	real	real	
DTAND	TAND	DTAND (d)	double	double	

Arcsine

ASIND	ASIND	ASIND (r)	real	real	
DASIND	ASIND	DASIND (d)	double	double	

Arccosine

ACOSD	ACOSD	ACOSD (r)	real	real	
DACOSD	DACOSD	DACOSD (d)	double	double	

Specific Name	Generic Name	Usage	Argument Type	Result Type	Notes
